Title General Equilibrium Modeling

Version 0.4.4

Author LI Wu <liwu@staff.shu.edu.cn>

Maintainer LI Wu <liwu.shu@qq.com>

Depends CGE, data.tree

Imports DiagrammeR

Description Some tools for developing general equilibrium models and some general equilibrium models. These models can be used for teaching economic theory and are built by the methods of new structural economics (see <https://www.nse.pku.edu.cn/> and LI Wu, 2019, ISBN: 9787521804225, General Equilibrium and Structural Dynamics: Perspectives of New Structural Economics. Beijing: Economic Science Press). The model form and mathematical methods can be traced back to J. von Neumann (1945, A Model of General Economic Equilibrium. The Review of Economic Studies, 13. pp. 1-9), J. G. Kemeny, O. Morgenstern and G. L. Thompson (1956, A Generalization of the von Neumann Model of an Expanding Economy, Econometrica, 24, pp. 115-135) et al. By the way, J. G. Kemeny is a co-inventor of the computer language BASIC.

AMSD *Additive-Mean-Variance Utility Function and Additive-Mean-Standard-Deviation Utility Function*

Description

Compute the utility function mean(x) - (gamma * sd.p(x))^theta / theta or weighted.mean(x, wt) - (gamma * sd.p(x, wt))^theta / theta.

Usage

```
AMSD(x, gamma = 1, wt = NULL, theta = 1)

AMV(x, gamma = 1, wt = NULL)
```

Arguments

x	a numeric n-vector.
gamma	a non-negative scalar representing the risk aversion coefficient with a default value of 1.
wt	a numeric n-vector of weights (or probability). If wt is NULL, all elements of x are given the same weight.
theta	a non-negative scalar with a default value of 1.

Value

A scalar indicating the utility level.

Functions

- AMSD: Computes the utility function mean(x) - (gamma * sd.p(x))^theta / theta or weighted.mean(x, wt) - (gamma * sd.p(x, wt))^theta / theta. When theta == 2, it is the additive mean-variance utility function (i.e. the function AMV). When theta == 1 (the default value), it is the additive mean and standard deviation utility function.
- AMV: Compute the additive mean-variance utility function mean(x) - 0.5 * gamma * var.p(x) or weighted.mean(x, wt) - 0.5 * gamma * var.p(x, wt).

References

Nakamura, Yutaka (2015). Mean-Variance Utility. Journal of Economic Theory, 160: 536-556.

Examples

```
AMSD(1:2, gamma = 0.05)
AMSD(1:2, gamma = 1, theta = 2)

marginal_utility(
  c(1, 1.001),
  c(0, 1), function(x) AMSD(x, gamma = 0.5)
)
marginal_utility(
  c(1.001, 1),
  c(0, 1), function(x) AMSD(x, gamma = 0.5)
)
```

AMSDP *Additive-Mean-Standard-Deviation Portfolio Utility Function*

Description

Compute the utility function x %*% mp - gamma^theta * (t(x) %*% Cov %*% x)^(0.5 * theta) / theta for a portfolio x.

Usage

```
AMSDP(x, mp, Cov, gamma = 1, theta = 1)
```

Arguments

x	a numeric n-vector representing a portfolio.
mp	a numeric n-vector representing the mean payoff of each of the n assets.
Cov	the n-by-n covariance matrix of the payoff vectors of n assets.
gamma	a non-negative scalar representing the risk aversion coefficient with a default value of 1.
theta	a non-negative scalar with a default value of 1.

Value

A scalar indicating the utility level.

apply_expand.grid *Applying a Function to All Combinations of the Supplied Vectors*

Description

A wrapper of the functions apply and expand.grid. Returns a data frame of values obtained by applying a function to all combinations of the supplied vectors. Firstly, the function expand.grid will be used for the supplied vectors in ... and we will get a data frame containing one row for each combination of the supplied vectors. Then the function will be applied to each row of the data frame. The values of the data frame will also be included in the returned data frame.

Usage

```
apply_expand.grid(FUN, ...)
```

Arguments

FUN	the function to be applied. The argument is a numeric vector.
...	numeric vectors.

Value

A data frame.

Examples

```
apply_expand.grid(prod, a = 1:9, b = 1:9)

####
f <- function(x) c(r1 = sum(x), r2 = unname(x["b"] - x["a"]))
apply_expand.grid(f, a = c(1, 2), b = c(3, 4))

####
f <- function(x) list(list(sum(x)), prod(x))
apply_expand.grid(f, a = c(1, 2), b = c(3, 4))

####
f <- function(x) {
  result <- SCES_A(alpha = 1, Beta = c(0.5, 0.5), p = c(x["p1"], 1), es = x["es"])
  names(result) <- c("dc1", "dc2")
  result
}

apply_expand.grid(f, p1 = seq(0.1, 10, 0.1), es = c(0.3, 0.5, 1))
```

CARA *Constant Absolute Risk Aversion (CARA) Utility Function*

Description

Compute the value and the certainty equivalent of the CARA utility function, i.e. -exp(-gamma*x). In general equilibrium analysis, the CARA utility function has an interval scale like temperature.

Usage

```
CARA(x, gamma, prob = rep(1/length(x), length(x)))
```

Arguments

x	a payoff k-vector.
gamma	the Arrow-Pratt measure of absolute risk aversion.
prob	a probability k-vector. By default, the states are assumed to occur with equal probability.

Value

A list containing the following components:

- u: the utility level.
- CE: the certainty equivalent.

Examples

```
mu <- 5 # mu <- 8
a <- 1
x <- c(mu - a, mu + a)
gamma <- 0.8
mu - CARA(x, gamma)$CE

####
gamma <- 0.8
mu <- 2
sigma <- 2
x <- seq(mu - 5 * sigma, mu + 5 * sigma, length.out = 10000)
# two CE calculation methods for random variables of normal distribution
CARA(x, gamma, dnorm(x, mean = mu, sd = sigma))
mu - gamma * sigma^2 / 2
```

CES *CES Function*

Description

CES function, e.g. alpha * (beta1 * (x1 / theta1)^sigma + beta2 * (x2 / theta2)^sigma)^(1 / sigma).

Usage

```
CES(sigma = 1 - 1/es, alpha, beta, x, theta = rep(1, length(beta)), es = NA)
```

Arguments

sigma	a scalar not greater than one.
alpha	a nonnegative scalar.
beta	a nonnegative n-vector.
x	a nonnegative n-vector consisting of the inputs.

theta	the all-ones n-vector (default) or a positive n-vector.
es	the elasticity of substitution. If es is not NA, the value of sigma (i.e. 1 - 1 / es) will be ignored.

Value

A scalar indicating the output or utility level.

Examples

```
CES(0.5, 1, c(0.4, 0.6), c(1, 1), c(0.4, 0.6))
CES(0.5, 1, c(0.4, 0.6), c(1, 2))
```

CESAK_dc *Demand coefficients of the CESAK Production Function*

Description

Computing the demand coefficients of the CESAK production function alpha * (betaK * x1^((es - 1) / es) + (1 - betaK) * x2^((es - 1) / es))^(es / (es - 1)) + alphaK * x1. When es==1, the CESAK production function becomes the CDAK production function alpha * x1^betaK * x2^(1 - betaK) + alphaK * x1.

Usage

```
CESAK_dc(alpha, betaK, alphaK, p, es = 1)
```

Arguments

alpha	a positive scalar.
betaK	a scalar between 0 and 1.
alphaK	a nonnegative scalar.
p	a 2-vector indicating the prices.
es	a nonnegative scalar specifying the elasticity of substitution.

Value

A 2-vector indicating the demand coefficients.

Examples

```
CESAK_dc(alpha = 1, betaK = 0.35, alphaK = 1 - 0.06, p = c(10, 1))
CESAK_dc(alpha = 1, betaK = 0.35, alphaK = 1 - 0.06, p = c(1, 10))
CESAK_dc(alpha = 1, betaK = 0.35, alphaK = 2, p = c(1, 1))

CESAK_dc(alpha = 1, betaK = 0.35, alphaK = 1 - 0.06, p = c(1, 1), es = 0.5)
CESAK_dc(alpha = 1, betaK = 0.35, alphaK = 0.1, p = c(1, 10), es = 0.5)
CESAK_dc(alpha = 1, betaK = 0.35, alphaK = 1.5, p = c(1, 10), es = 0.5)
```

CRRA *Constant Relative Risk Aversion (CRRA) Utility Function*

Description

Compute the value and the certainty equivalent of the CRRA utility function.

Usage

```
CRRA(x, gamma, prob = rep(1/length(x), length(x)))
```

Arguments

x	a payoff k-vector.
gamma	the relative risk aversion coefficient.
prob	a probability k-vector. By default, the states are assumed to occur with equal probability.

Value

A list containing the following components:

- u: the utility level.
- CE: the certainty equivalent.

Examples

```
csv <- 0.05 # coefficient of standard deviation
mu <- 90 # mu <- 100
sigma <- mu * csv
x <- seq(mu - 5 * sigma, mu + 5 * sigma, length.out = 10000)
pd <- dnorm(x, mean = mu, sd = sigma)
gamma <- 0.8
# the ratio of risk premium to expected return (i.e. the relative risk premium).
(mu - CRRA(x, gamma, pd)$CE) / mu
```

```
####
df <- apply_expand.grid(
  function(arg) {
    CRRA(arg["x"], arg["gamma"])$u
  },
  x = seq(0.5, 3, 0.1),
  gamma = c(0.5, 1, 2, 3)
)
coplot(result ~ x | as.factor(gamma), data = df)
```

DCES *Displaced CES Utility Function and Displaced CES Demand Function*

Description

The displaced CES utility function and the displaced CES demand function (Fullerton, 1989).

Usage

```
DCES(es, beta, xi, x)

DCES_demand(es, beta, xi, w, p)

DCES_compensated_demand(es, beta, xi, u, p)

DCES_indirect(es, beta, xi, w, p)
```

Arguments

es	a scalar indicating the elasticity of substitution.
beta	an n-vector consisting of the marginal expenditure share coefficients. The sum of all components of beta should be 1.
xi	an n-vector or a scalar. If xi is a scalar, it will be recycled to an n-vector. Each element of xi parameterizes whether the particular good is a necessity for the household (Acemoglu, 2009, page 152). For example, xi[i] > 0 may mean that the household needs to consume at least a certain amount of good i to survive.
x	an n-vector consisting of the inputs.
w	a scalar indicating the income.
p	an n-vector indicating the prices.
u	a scalar indicating the utility level.

Value

The return values of these functions are as follows:
DCES: A scalar indicating the utility level.
DCES_demand: An n-vector indicating the demands.
DCES_compensated_demand: An n-vector indicating the compensated demands.
DCES_indirect: A scalar indicating the utility level.

Functions

- `DCES`: Compute the displaced CES utility function (Fullerton, 1989), e.g. (beta1 ^ (1 / es) * (x1 - xi1) ^ (1 - 1 / es) + beta2 ^ (1 / es) * (x2 - xi2) ^ (1 - 1 / es)) ^ (es / (es - 1) wherein beta1 + beta2 == 1.

  When es==1, the DCES utility function becomes the Stone-Geary utility function.
- `DCES_demand`: The displaced CES demand function (Fullerton, 1989).
- `DCES_compensated_demand`: The displaced CES compensated demand function (Fullerton, 1989).
- `DCES_indirect`: The displaced CES indirect utility function (Fullerton, 1989).

`demand_coefficient` *Compute Demand Coefficients of an Agent with a Demand Structural Tree*

Description

Given a price vector, this function computes the demand coefficients of an agent with a demand structural tree. The class of a demand structural tree is Node defined by the package data.tree.

Usage

```
demand_coefficient(node, p, trace = FALSE)
```

Arguments

`node`	a demand structural tree.
`p`	a price vector with names of commodities.
`trace`	FALSE (default) or TRUE. If TRUE, calculation intermediate results will be recorded in nodes.

Details

Demand coefficients often indicate the quantity of various commodities needed by an economic agent in order to obtain a unit of output or utility, and these commodities can include both real commodities and financial instruments such as tax receipts, stocks, bonds and currency.
The demand for various commodities by an economic agent can be expressed by a demand structure tree. Each non-leaf node can be regarded as the output of all its child nodes. Each node can be regarded as an input of its parent node. In other words, the commodity represented by each non-leaf node is a composite commodity composed of the commodities represented by its child nodes. Each non-leaf node usually has an attribute named type. This attribute describes the input-output relationship between the child nodes and the parent node. This relationship can sometimes be represented by a production function or a utility function. The type attribute of each non-leaf node can take the following values.

- SCES. In this case, this node also has parameters alpha, beta and es (or sigma = 1 - 1 / es). alpha and es are scalars. beta is a vector. These parameters are parameters of a standard CES function (see `SCES` and `SCES_A`).
- CES. In this case, this node also has parameters alpha, beta, theta (optional) and es (or sigma = 1 - 1 / es) (see CGE::CES_A).
- Leontief. In this case, this node also has the parameter a, which is a vector and is the parameter of a Leontief function.
- CD. CD is Cobb-Douglas. In this case, this node also has parameters alpha and beta, which are parameters of a Cobb-Douglas function.
- CESAK. In this case, this node also has parameters es, alpha, betaK and alphaK, which are parameters of the CESAK function (see `CESAK_dc`). Moreover, the first child node should represent capital goods.

- FIN. That is the financial type. In this case, this node also has the parameter rate or beta. If the parameter beta is not NULL, then the parameter rate will be ignored. The parameter rate applies to all situations, while the parameter beta only applies for some special cases. For FIN nodes, the first child node should represent for a physical commodity or a composite commodity containing a physical commodity, and other child nodes represent for financial instruments. The parameter beta indicates the proportion of each child node's expenditure. The parameter rate indicates the expenditure ratios between financial-instrument-type child nodes and the first child node. The first element of the parameter rate indicates the amount of the first child node needed to get a unit of output.
- FUNC. That is the function type. In this case, this node also has an attribute named func. The value of that attribute is a function which calculates the demand coefficient for the child nodes. The argument of that function is a price vector. The length of that price vector is equal to the number of the child nodes.
- StickyLinear or SL. That is the sticky linear type. In this case, this node also has an attribute named beta that contains the coefficients of the linear utility or production function. In order to avoid too drastic changes in the demand structure, the adjustment process of the demand structure has a certain stickiness when prices change.

Value

A vector consisting of demand coefficients.

Examples

```
#### a Leontief-type node
dst <- node_new("firm",
  type = "Leontief", a = c(0.5, 0.1),
  "wheat", "iron"
)
print(dst, "type")
node_print(dst)
plot(dst)
node_plot(dst, TRUE)

demand_coefficient(dst, p = c(wheat = 1, iron = 2)) # the same as a = c(0.5, 0.1)

#### a CD-type node
dst <- node_new("firm",
  type = "CD", alpha = 1, beta = c(0.5, 0.5),
  "wheat", "iron"
)

demand_coefficient(dst, p = c(wheat = 1, iron = 2))
# the same as the following
CD_A(1, c(0.5, 0.5), c(1, 2))

#### a SCES-type node
dst <- node_new("firm",
  type = "SCES",
  alpha = 2, beta = c(0.8, 0.2), es = 0.5,
  "wheat", "iron"
```

```
)

demand_coefficient(dst, p = c(wheat = 1, iron = 2))

# the same as the following

  "product", "labor"
)

node_plot(dst)
demand_coefficient(dst, p)
```

`demCreditPolicy` *A Disequilibrium Model with Credit*

Description

These are some examples to illustrate that credit policies may lead to business cycles. When the firm's profit rate is high, the laborer lends labor or labor income to the firm; when the firm's profit rate is low, the firm repays the loan with products.

Usage

```
demCreditPolicy(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
dst.firm <- node_new("output",
  type = "CD", alpha = 1.2,
  beta = c(0.5, 0.5),
  "prod", "lab"
)

dst.consumer <- node_new("utility",
  type = "Leontief", a = 1,
  "prod"
)

f <- function(policy = NULL) {
  ge <- sdm2(
    A = list(dst.firm, dst.consumer),
    B = matrix(c(
      1, 0,
      0, 1
    ), 2, 2, TRUE),
    S0Exg = matrix(c(
      NA, NA,
      NA, 100
    ), 2, 2, TRUE),
    names.commodity = c("prod", "lab"),
    names.agent = c("firm", "consumer"),
    ts = TRUE,
    policy = policy,
    numberOfPeriods = 200,
    maxIteration = 1,
    priceAdjustmentVelocity = 0.05
  )

  matplot(ge$ts.z, type = "o", pch = 20)
  ge
}

## no credit policy
ge <- f()

`demInsufficientEffectiveDemand_3_3` *A Disequilibrium Model Illustrating Insufficient Effective Demand (Supply-demand Structural Mismatch)*

Description

A disequilibrium model illustrating supply-demand structural mismatch and insufficient effective demand. Assume that from the 5th period, the producer expects the sales rate of products to decline, so he reduces investment in production and increases the demand for value storage means (such as foreign assets, gold, etc.); the laborer expects the unemployment rate to rise, so he reduces consumption and increases the demand for value storage means.

Here the supplier of value storage means is referred to as ROW (the rest of the world).

Usage

```
demInsufficientEffectiveDemand_3_3(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
dst.firm <- node_new("output",

`gemAssetExchange_MatthewEffect_2_2` *An Example Illustrating the Matthew Effect of Asset Exchange*

Description

This is an example that illustrates the Matthew effect of asset exchange, wherein the wealth gap between two traders widens after the exchange process. Initially, these traders had a relatively small wealth (i.e. expected average payoff) gap. However, the exchange leads to an expansion of the wealth gap. This outcome can be attributed to the fact that a trader's risk aversion coefficient is affected by his level of wealth. When traders have less wealth their risk aversion coefficient is higher. Consequently, a trader with less wealth tends to acquire more low-risk, low-average-payoff assets through trading. As a result, the expected average payoff of a trader with less wealth may decrease after the exchange. Conversely, a trader with more wealth may hold more high-risk, high-average-payoff assets after trading.

Usage

```
gemAssetExchange_MatthewEffect_2_2(...)
```

Arguments

...	arguments to be passed to the function sdm2.

`gemAssetPricingExample` *Some Examples of Asset Pricing*

Description

These examples illustrate how to find the equilibrium of an asset market by the function sdm2 and by computing marginal utility of assets (see Sharpe, 2008).

Usage

```
gemAssetPricingExample(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Value

A general equilibrium.

`gemAssetPricing_CUF` *Compute Asset Market Equilibria with Commodity Utility Functions for Some Simple Cases*

Description

Compute the equilibrium of an asset market by the function sdm2 and by computing marginal utility of assets (see Sharpe, 2008). The argument of the utility function used in the calculation is the commodity vector (i.e. payoff vector).

Usage

```
gemAssetPricing_CUF(
  S = diag(2),
  UAP = diag(nrow(S)),
  uf = NULL,
  muf = NULL,
  ratio_adjust_coef = 0.05,
  numeraire = 1,
  ...
)
```

Arguments

`S`	an n-by-m supply matrix of assets.
`UAP`	a unit asset payoff k-by-n matrix.
`uf`	a utility function or a utility function list.
`muf`	a marginal utility function or a marginal utility function list.
`ratio_adjust_coef`	a scalar indicating the adjustment velocity of demand structure.
`numeraire`	the index of the numeraire commodity.
`...`	arguments to be passed to the function sdm2.

Value

A general equilibrium containing a value marginal utility matrix (VMU).

`gemAssetPricing_PUF` *Compute Asset Market Equilibria with Portfolio Utility Functions for Some Simple Cases*

Description

Compute the equilibrium of an asset market by the function sdm2 and by computing marginal utility of assets. The argument of the utility function used in the calculation is the asset vector (i.e. portfolio).

Usage

```
gemAssetPricing_PUF(S, uf, numeraire = nrow(S), ratio_adjust_coef = 0.1, ...)
```

Arguments

`S`	an n-by-m supply matrix of assets.
`uf`	a portfolio utility function or a list of m portfolio utility functions.
`numeraire`	the index of the numeraire commodity.
`ratio_adjust_coef`	a scalar indicating the adjustment velocity of demand structure.
`...`	arguments to be passed to the function sdm2.

Value

A general equilibrium containing a value marginal utility matrix (VMU).

`gemCanonicalDynamicMacroeconomic_3_2` *A Canonical Dynamic Macroeconomic General Equilibrium Model (see Torres, 2016)*

Description

A canonical dynamic macroeconomic general equilibrium model (see Torres, 2016, Table 2.1 and 2.2).

Usage

```
gemCanonicalDynamicMacroeconomic_3_2(
  discount.factor = 0.97,
  depreciation.rate = 0.06,
  beta.prod.firm = 0.35,
  beta.prod.consumer = 0.4,
  policy.supply = NULL,
  policy.technology = NULL,
  policy.price = NULL,
  ...
)
```

Arguments

`discount.factor`	the intertemporal discount factor.
`depreciation.rate`	the physical depreciation rate of capital stock.
`beta.prod.firm`	the share parameter of the product in the Cobb-Douglas production function.
`beta.prod.consumer`	the share parameter of the product in the Cobb-Douglas period utility function. This parameter represents the individual's preferences regarding consumption-leisure decisions.
`policy.supply`	a policy function or a policy function list which adjusts the supplies.
`policy.technology`	a policy function or a policy function list which adjusts the technology.
`policy.price`	a policy function or a policy function list which adjusts the prices.
`...`	arguments to be to be passed to the function sdm2.

Details

A general equilibrium model with 3 commodities (i.e. product, labor and equity shares) and 2 agents (i.e. a firm and a consumer). Labor is the numeraire.

Value

A general equilibrium (see sdm2).

`gemCanonicalDynamicMacroeconomic_4_3` *A Canonical Dynamic Macroeconomic General Equilibrium Model (see Torres, 2016)*

Description

A canonical dynamic macroeconomic general equilibrium model (see Torres, 2016, Table 2.1 and 2.2).

Usage

```
gemCanonicalDynamicMacroeconomic_4_3(
  discount.factor = 0.97,
  depreciation.rate = 0.06,
  beta.prod.firm = 0.35,
  beta.prod.consumer = 0.4,
  ...
)
```

Arguments

`discount.factor`	the intertemporal discount factor.
`depreciation.rate`	the physical depreciation rate of capital stock.
`beta.prod.firm`	the share parameter of the product in the Cobb-Douglas production function of the production firm.
`beta.prod.consumer`	the share parameter of the product in the Cobb-Douglas period utility function of the consumer.
`...`	arguments to be to be passed to the function sdm2.

Details

A general equilibrium model with 4 commodities (i.e. product, labor, capital and equity shares) and 3 agents (i.e. a production firm, a consumer and a capital-leasing firm).

Value

A general equilibrium (see sdm2)

gemCanonicalDynamicMacroeconomic_Sequential_3_2

A Canonical Dynamic Macroeconomic General Equilibrium Model in Sequential Form (see Torres, 2016)

Description

A canonical dynamic macroeconomic general equilibrium model in sequential form (see Torres, 2016, Table 2.1 and 2.2).

Usage

```
gemCanonicalDynamicMacroeconomic_Sequential_3_2(
  alpha.firm = 1,
  es.prod.lab.firm = 1,
  beta.prod.firm = 0.35,
  depreciation.rate = 0.06,
  eis = 1,
  Gamma.beta = 0.97,
  es.prod.lab.consumer = 1,
  beta.prod.consumer = 0.4,
  gr = 0,
  wage.payment = "post",
  ...
)
```

Arguments

alpha.firm	a positive scalar, indicating the efficiency parameter of the firm.
es.prod.lab.firm	the elasticity of substitution between product and labor in the production function of firm 1.
beta.prod.firm	the share parameter of the product in the production function.
depreciation.rate	the physical depreciation rate of capital stock.

`eis`	the elasticity of intertemporal substitution of the consumer.
`Gamma.beta`	the subjective discount factor of the consumer.
`es.prod.lab.consumer`	the elasticity of substitution between product and labor in the CES-type period utility function of the consumer.
`beta.prod.consumer`	the share parameter of the product in the period utility function.
`gr`	the growth rate of the labor supply.
`wage.payment`	a character string specifying the wage payment method, must be one of "pre" or "post". See the note below.
`...`	arguments to be passed to the function sdm2.

Value

A general equilibrium (see sdm2).

Note

In the timeline model and the time-circle model, we refer to the labor provided in period t as labor t, and the product produced by using labor t as product t+1. When the consumer's period utility function simultaneously includes labor (or leisure) and product, we can choose from one of two assumptions: it can be assumed that the period utility function of the consumer in period t includes labor t and product t, or it can be assumed that it includes labor t and product $t+1$. These two assumptions are respectively referred to as the wage prepayment assumption and the wage postpayment assumption.

`gemCanonicalDynamicMacroeconomic_Sequential_WagePostpayment_4_3`
A Canonical Dynamic Macroeconomic General Equilibrium Model in Sequential Form under the Wage Postpayment Assumption (see Torres, 2016)

Description

A canonical dynamic macroeconomic general equilibrium model in sequential form under the wage postpayment assumption (see Torres, 2016, Table 2.1 and 2.2). In this model, there are two firms and one consumer. Under the wage postpayment assumption, the consumer actually consumes a kind of labor (that is, leisure) and the products produced by this labor at the same time. Firm 1 is a regular production firm. Firm 2 can store labor from one period to the next period for consumption by the consumer.

Usage

```
gemCanonicalDynamicMacroeconomic_Sequential_WagePostpayment_4_3(
  alpha.firm = 1,
  es.prod.lab.firm = 1,
  beta.prod.firm = 0.35,
  depreciation.rate = 0.06,
  eis = 1,
```

```
  Gamma.beta = 0.97,
  es.prod.lab.consumer = 1,
  beta.prod.consumer = 0.4,
  gr = 0,
  ...
)
```

Arguments

alpha.firm	a positive scalar, indicating the efficiency parameter of firm 1.
es.prod.lab.firm	the elasticity of substitution between product and labor in the production function of firm 1.
beta.prod.firm	the share parameter of the product in the production function of firm 1.
depreciation.rate	the physical depreciation rate of capital stock of firm 1.
eis	the elasticity of intertemporal substitution of the consumer.
Gamma.beta	the subjective discount factor of the consumer.
es.prod.lab.consumer	the elasticity of substitution between product and labor in the CES-type period utility function of the consumer.
beta.prod.consumer	the share parameter of the product in the period utility function.
gr	the growth rate of the labor supply.
...	arguments to be passed to the function sdm2.

Value

A general equilibrium (see sdm2).

ge$S[1, 1] * (1 + gr)
```

`gemCanonicalDynamicMacroeconomic_TimeCircle_2_2`
A Canonical Dynamic Macroeconomic General Equilibrium Model in Time-circle Form (see Torres, 2016)

Description

A canonical dynamic macroeconomic general equilibrium model in time-circle form (see Torres, 2016, Table 2.1 and 2.2).

Usage

```
gemCanonicalDynamicMacroeconomic_TimeCircle_2_2(
  alpha.firm = rep(1, 3),
  es.prod.lab.firm = 1,
  beta.prod.firm = 0.35,
  depreciation.rate = 0.06,
  eis = 1,
  Gamma.beta = 0.97,
  beta.prod.consumer = 0.4,
  es.prod.lab.consumer = 1,
  gr = 0,
  wage.payment = "post",
  ...
)
```

Arguments

`alpha.firm`	a positive vector, indicating the efficiency parameters of the firm for each economic period. The number of economic periods will be set to length(alpha.firm) .
`es.prod.lab.firm`	the elasticity of substitution between product and labor in the production function of the firm.
`beta.prod.firm`	the share parameter of the product in the production function.

depreciation.rate
: the physical depreciation rate of capital stock.

eis
: the elasticity of intertemporal substitution of the consumer.

Gamma.beta
: the subjective discount factor of the consumer.

beta.prod.consumer
: the share parameter of the product in the period utility function.

es.prod.lab.consumer
: the elasticity of substitution between product and labor in the CES-type period utility function of the consumer.

gr
: the growth rate of the labor supply.

wage.payment
: a character string specifying the wage payment method, must be one of "pre" or "post".

...
: arguments to be passed to the function sdm2.

Value

A general equilibrium (see sdm2).

`gemCanonicalDynamicMacroeconomic_Timeline_2_2`
A Canonical Dynamic Macroeconomic General Equilibrium Model in Timeline Form (see Torres, 2016)

Description

A canonical dynamic macroeconomic general equilibrium model in timeline form (see Torres, 2016, Table 2.1 and 2.2). The firm has a CESAK production function.

Usage

```
gemCanonicalDynamicMacroeconomic_Timeline_2_2(
  alpha.firm = rep(1, 4),
  es.prod.lab.firm = 1,
  beta.prod.firm = 0.35,
  depreciation.rate = 0.06,
  eis = 1,
  Gamma.beta = 0.97,
  beta.prod.consumer = 0.4,
  es.prod.lab.consumer = 1,
  gr = 0,
  initial.product.supply = 200,
  head.tail.adjustment = "both",
  wage.payment = "post",
  beta.consumer = NULL,
  ...
)
```

Arguments

`alpha.firm`	a positive vector, indicating the efficiency parameters of the firm for each economic period. The number of economic periods will be set to length(alpha.firm) + 1.
`es.prod.lab.firm`	the elasticity of substitution between product and labor in the production function of the firm.

`beta.prod.firm` the share parameter of the product in the production function.

`depreciation.rate`
: the physical depreciation rate of capital stock.

`eis` a positive scalar indicating the elasticity of intertemporal substitution of the consumer.

`Gamma.beta` the subjective discount factor of the consumer.

`beta.prod.consumer`
: the share parameter of the product in the period utility function.

`es.prod.lab.consumer`
: the elasticity of substitution between product and labor in the CES-type period utility function of the consumer.

`gr` the growth rate of the labor supply.

`initial.product.supply`
: the initial product supply.

`head.tail.adjustment`
: a character string specifying the type of the head-tail-adjustment policy, must be one of "both" (default), "head", "tail" or "none".

`wage.payment` a character string specifying the wage payment method, must be one of "pre" or "post".

`beta.consumer` NULL (the default) or a positive vector containing length(alpha.firm) + 1 elements specifying the consumer's intertemporal share parameter. If beta.consumer is not NULL, Gamma.beta will be ignored.

`...` arguments to be passed to the function sdm2.

`gemDualLinearProgramming` *General Equilibrium Models and Linear Programming Problems (see Winston, 2003)*

Description

Some examples illustrating the relationship between general equilibrium problems and (dual) linear programming problems. Some linear programming problems can be transformed into general equilibrium problems and vice versa.

Usage

```
gemDualLinearProgramming(...)
```

Arguments

...	arguments to be passed to the function CGE::sdm.

Details

These examples are similar and let us explain briefly the first example (Winston, 2003).
The Dakota Furniture Company manufactures desks, tables, and chairs. The manufacture of each type of furniture requires lumber and two types of skilled labor: finishing and carpentry. The amount of each resource needed to make each type of furniture is as follows:
desk: (8, 4, 2)
table: (6, 2, 1.5)
chair: (1, 1.5, 0.5)
Currently, 48 board feet of lumber, 20 finishing hours, and 8 carpentry hours are available. A desk sells for $60, a table for $30, and a chair for $20. Because the available resources have already been purchased, Dakota wants to maximize total revenue. This problem can be solved by the linear programming method.
Now let us regard the problem above as a general equilibrium problem. The Dakota Furniture Company can be regarded as a consumer who obtains 1 unit of utility from 1 dollar and owns lumber and two types of skilled labor. There are four commodities (i.e. dollar, lumber and two types of skilled labor) and four agents (i.e. a desk producer, a table producer, a chair producer and the consumer Dakota) in this problem. We need to compute the equilibrium activity levels and the equilibrium prices, which are also the solutions of the (dual) linear programming problems (i.e. the utility-maximizing problem of the consumer and the cost-minimizing problem of the producers).

Value

A general equilibrium.

Note

Below is a simplified form of the von Neumann general equilibrium model (von Neumann, 1945; Kemeny, Morgenstern, Thompson, 1956):

$$\mathbf{p}^T\mathbf{A} \geq \rho\mathbf{p}^T\mathbf{B}$$

$$\mathbf{A}\mathbf{z} \leq \rho\mathbf{B}\mathbf{z}$$

The above model can be extended to the following general equilibrium model, namely the structural equilibrium model (Li, 2019, section 3.4):

$$\mathbf{p}^T\mathbf{A}(\mathbf{p},\mathbf{u},\mathbf{z}) \geq \rho\mathbf{p}^T\mathbf{B}(\mathbf{p},\mathbf{u},\mathbf{z})$$

$$\mathbf{A}(\mathbf{p},\mathbf{u},\mathbf{z})\mathbf{z} \leq \rho\mathbf{B}(\mathbf{p},\mathbf{u},\mathbf{z})\mathbf{z}$$

We explain the structural equilibrium model as follows:
(i) The vectors $\mathbf{p}$ and $\mathbf{z}$ reflect the prices of various commodities and the activity levels of various economic agents, respectively.
(ii) The vector $\mathbf{u}$ reflects the utility levels of various consumers. In this model, the matrices $\mathbf{A}$ and $\mathbf{B}$ are functions of prices, utilities, and activity levels.
(iii) When describing a static general equilibrium and a steady-state equilibrium without intertemporal decisions, the structural equilibrium model usually does not explicitly include time, while when describing an intertemporal general equilibrium, variables such as prices and activity levels explicitly include time, that is, they are labeled with time.
(iv) In a time-independent model, ρ is the discount factor $\frac{1}{1+\gamma}$ corresponding to the steady-state growth rate γ. In a time-dependent model, ρ is usually equal to 1.
(v) The unit demand matrix $\mathbf{A}(\mathbf{p},\mathbf{u},\mathbf{z})$, the unit supply matrix $\mathbf{B}(\mathbf{p},\mathbf{u},\mathbf{z})$ and the activity level vector $\mathbf{z}$ in the structural equilibrium model are different from the input coefficient matrix A, the output coefficient matrix B and the purchase level vector z in the structural dynamic model. The input coefficient matrix A is equivalent to the unit demand matrix with utility levels equal to 1. The output coefficient matrix B, unlike the unit supply matrix, does not contain the exogenous supplies. In the structural equilibrium model, the elements corresponding to consumers in $\mathbf{z}$ usually reflect the number of consumers, while in the structural dynamic model, they usually reflect the utility levels.

Now consider the following linear programming problem:

$$\max \quad \mathbf{b}^T\mathbf{z} \quad \text{s.t.} \quad \mathbf{A}\mathbf{z} \leq \mathbf{e}, \quad \mathbf{z} \geq \mathbf{0}$$

The dual linear programming problem is

$$\min \quad \mathbf{p}^T\mathbf{e} \quad \text{s.t.} \quad \mathbf{p}^T\mathbf{A} \geq \mathbf{b}, \quad \mathbf{p} \geq \mathbf{0}$$

In the example of Winston (2003), we have $\mathbf{e} = (48, 20, 8)^T$, $\mathbf{b} = (60, 30, 20)^T$ and

$$\mathbf{A} = \begin{bmatrix} 8 & 6 & 1 \\ 4 & 2 & 1.5 \\ 2 & 1.5 & 0.5 \end{bmatrix}$$

The corresponding structural equilibrium model is

$$\mathbf{p}^T\mathbf{A}(u) \geq \mathbf{p}^T\mathbf{B}$$

$$\mathbf{A}(u)\mathbf{z} \leq \mathbf{B}\mathbf{z}$$

wherein $\mathbf{p} = (1, p_2, p_3, p_4)^T$, $\mathbf{z} = (z_1, z_2, z_3, 1)^T$,

$$\mathbf{A}(u) = \begin{bmatrix} 0 & 0 & 0 & u \\ 8 & 6 & 1 & 0 \\ 4 & 2 & 1.5 & 0 \\ 2 & 1.5 & 0.5 & 0 \end{bmatrix}$$

and

$$\mathbf{B} = \begin{bmatrix} 60 & 30 & 20 & 0 \\ 0 & 0 & 0 & 48 \\ 0 & 0 & 0 & 20 \\ 0 & 0 & 0 & 8 \end{bmatrix}$$

The following results are obtained by solving the above structural equilibrium model:

$$\mathbf{p}^* = (1, 0, 10, 10)^T, \quad \mathbf{z}^* = (2, 0, 8, 1)^T, \quad u^* = 280$$

gemInputOutputTable_2_7_2

A Two-Country General Equilibrium Model

Description

A two-country general equilibrium model. This general equilibrium model is based on a two-country (i.e. CHN and ROW) input-output table consisting of an input part and an output part. Each country contains 2 sectors and 7 commodities (or subjects). The 2 sectors are firm and household. The 7 commodities (or subjects) are product, labor, capital goods, bond, tax, dividend, tariff. Hence the input-output table has 14 rows and 4 columns.

Usage

```
gemInputOutputTable_2_7_2(
  IT,
  OT,
  es.DIProduct.firm.CHN = 3,
  es.DIProduct.firm.ROW = 3,
  es.laborCapital.firm.CHN = 0.75,
  es.laborCapital.firm.ROW = 0.75,
  es.household.CHN = 3,
  es.household.ROW = 3,
  return.dstl = FALSE,
  ...
)
```

Arguments

IT	the input part of the input-output table.
OT	the output part of the input-output table.
es.DIProduct.firm.CHN	the elasticity of substitution between domestic product and imported product used by the production sector of CHN.
es.DIProduct.firm.ROW	the elasticity of substitution between domestic product and imported product used by the production sector of ROW.
es.laborCapital.firm.CHN	the elasticity of substitution between labor and capital goods used by the production sector of CHN.

`es.laborCapital.firm.ROW`
: the elasticity of substitution between labor and capital goods used by the production sector of ROW.

`es.household.CHN`
: the elasticity of substitution between domestic product and imported product used by the consumption sector of CHN.

`es.household.ROW`
: the elasticity of substitution between domestic product and imported product used by the consumption sector of ROW.

`return.dstl`
: If TRUE, the demand structure tree will be returned.

`...`
: arguments to be transferred to the function `sdm2`.

Value

A general equilibrium, which usually is a list with the following elements:

- p - the price vector with CHN labor as numeraire.
- dstl - the demand structure tree list of sectors if return.dstl == TRUE.
- ... - some elements returned by the function `sdm2`.

Examples

```
IT <- matrix(c(
  142, 84, 13, 4.1,
  47, 0, 0, 0,

`gemInputOutputTable_2_7_4` *A Two-Country General Equilibrium Model*

Description

A two-country general equilibrium model. This general equilibrium model is based on a two-country (i.e. CHN and ROW) input-output table consisting of an input part and an output part. Each country contains 4 sectors and 7 commodities (or subjects). The 4 sectors are production, consumption, investment and foreign trade. The 7 commodities (or subjects) are product, labor, capital goods, bond, tax, dividend, imported product. Hence the input-output table has 14 rows and 8 columns.

Usage

```
gemInputOutputTable_2_7_4(
  IT,
  OT,
  es.DIProduct.production.CHN = 3,
  es.DIProduct.production.ROW = 3,
  es.laborCapital.production.CHN = 0.75,
  es.laborCapital.production.ROW = 0.75,
  es.consumption.CHN = 3,
  es.consumption.ROW = 3,
  es.investment.CHN = 3,
  es.investment.ROW = 3,
  return.dstl = FALSE,
  ...
)
```

Arguments

IT	the input part of the input-output table.
OT	the output part of the input-output table.

es.DIProduct.production.CHN
: the elasticity of substitution between domestic product and imported product used by the production sector of CHN.

es.DIProduct.production.ROW
: the elasticity of substitution between domestic product and imported product used by the production sector of ROW.

es.laborCapital.production.CHN
: the elasticity of substitution between labor and capital goods used by the production sector of CHN.

es.laborCapital.production.ROW
: the elasticity of substitution between labor and capital goods used by the production sector of ROW.

es.consumption.CHN
: the elasticity of substitution between domestic product and imported product used by the consumption sector of CHN.

es.consumption.ROW
: the elasticity of substitution between domestic product and imported product used by the consumption sector of ROW.

es.investment.CHN
: the elasticity of substitution between domestic product and imported product used by the investment sector of CHN.

es.investment.ROW
: the elasticity of substitution between domestic product and imported product used by the investment sector of ROW.

return.dstl
: If TRUE, the demand structure tree will be returned.

...
: arguments to be transferred to the function sdm2.

Value

A general equilibrium, which usually is a list with the following elements:

- p - the price vector with CHN labor as numeraire.
- dstl - the demand structure tree list of sectors if return.dstl == TRUE.
- ... - some elements returned by the function sdm2.

gemInputOutputTable_2_8_4 *A Two-Country General Equilibrium Model with Money*

Description

A two-country general equilibrium model with money. This general equilibrium model is based on a two-country (i.e. CHN and ROW) input-output table. Each country contains four sectors and eight commodities (or subjects). The four sectors are production, consumption, investment and foreign trade. The eight commodities (or subjects) are product, labor, capital goods, bond, tax, dividend, imported product and money interest. Hence the input-output table has 16 rows and 8 columns.

Usage

```
gemInputOutputTable_2_8_4(
  IT,
  product.output.CHN = sum(IT[, "production.CHN"]),
  product.output.ROW = sum(IT[, "production.ROW"]),
  labor.supply.CHN = sum(IT["labor.CHN", ]),
  labor.supply.ROW = sum(IT["labor.ROW", ]),
  capital.supply.CHN = sum(IT["capital.CHN", ]),
  capital.supply.ROW = sum(IT["capital.ROW", ]),
  money.interest.supply.CHN = 5,
  money.interest.supply.ROW = 30,
  es.DIProduct.production.CHN = 0.5,
```

```
  es.DIProduct.production.ROW = 0.5,
  es.laborCapital.production.CHN = 0.75,
  es.laborCapital.production.ROW = 0.75,
  es.consumption.CHN = 0.5,
  es.consumption.ROW = 0.5,
  es.investment.CHN = 0.9,
  es.investment.ROW = 0.9,
  interest.rate.CHN = NA,
  interest.rate.ROW = NA,
  return.dstl = FALSE,
  ...
)
```

Arguments

`IT`	the input part of the input-output table (unit: trillion yuan).
`product.output.CHN`	the product output of the production sector of CHN.
`product.output.ROW`	the product output of the production sector of ROW.
`labor.supply.CHN`	the labor supply of CHN.
`labor.supply.ROW`	the labor supply of ROW.
`capital.supply.CHN`	the capital supply of CHN.
`capital.supply.ROW`	the capital supply of ROW.
`money.interest.supply.CHN`	the money interest supply of CHN, that is, the exogenous money supply multiplied by the exogenous interest rate.
`money.interest.supply.ROW`	the money interest supply of ROW.
`es.DIProduct.production.CHN`	the elasticity of substitution between domestic product and imported product used by the production sector of CHN.
`es.DIProduct.production.ROW`	the elasticity of substitution between domestic product and imported product used by the production sector of ROW.
`es.laborCapital.production.CHN`	the elasticity of substitution between labor and capital goods used by the production sector of CHN.
`es.laborCapital.production.ROW`	the elasticity of substitution between labor and capital goods used by the production sector of ROW.

`es.consumption.CHN`
: the elasticity of substitution between domestic product and imported product used by the consumption sector of CHN.

`es.consumption.ROW`
: the elasticity of substitution between domestic product and imported product used by the consumption sector of ROW.

`es.investment.CHN`
: the elasticity of substitution between domestic product and imported product used by the investment sector of CHN.

`es.investment.ROW`
: the elasticity of substitution between domestic product and imported product used by the investment sector of ROW.

`interest.rate.CHN`
: the interest rate of CHN.

`interest.rate.ROW`
: the interest rate of ROW.

`return.dstl`
: If TRUE, the demand structure tree will be returned.

`...`
: arguments to be transferred to the function `sdm2`.

Details

If interest.rate.CHN is NA or interest.rate.CHN is NA, they are assumed to be equal. And in this case, the exchange rate is determined by the ratio of the interest of unit currency of the two countries. In this model, the ratio of a sector's monetary interest expenditure to its transaction value may not be equal to the interest rate because the ratio is not only affected by the interest rate, but also by the sector's currency circulation velocity and other factors.

Value

A general equilibrium, which usually is a list with the following elements:

- p - the price vector with CHN labor as numeraire, wherein the price of a currency is the interest per unit of currency.
- D - the demand matrix, also called the input table. Wherein the benchmark prices are used.
- DV - the demand value matrix, also called the value input table. Wherein the current price is used.
- SV - the supply value matrix, also called the value output table. Wherein the current price is used.
- eri.CHN - the exchange rate index of CHN currency.
- eri.ROW - the exchange rate index of ROW currency.
- p.money - the price vector with CHN money as numeraire if both interest.rate.CHN and interest.rate.CHN are not NA.
- dstl - the demand structure tree list of sectors if return.dstl == TRUE.
- ... - some elements returned by the function `sdm2`.

Examples

```
ITExample <- matrix(0, 16, 8, dimnames = list(
  c(
    "product.CHN", "labor.CHN", "capital.CHN", "bond.CHN",
    "tax.CHN", "dividend.CHN", "imported.product.CHN", "money.interest.CHN",

`gemInputOutputTable_5_4` *A General Equilibrium Model based on a 5×4 Input-Output Table (see Zhang Xin, 2017, Table 8.6.1)*

Description

This is a general equilibrium model based on a 5×4 input-output table (see Zhang Xin, 2017, Table 8.6.1).

Usage

```
gemInputOutputTable_5_4(
  dstl,
  supply.labor = 850,
  supply.capital = 770,
  names.commodity = c("agri", "manu", "serv", "lab", "cap"),
  names.agent = c("agri", "manu", "serv", "hh")
)
```

Arguments

`dstl`	a demand structure tree list.
`supply.labor`	the supply of labor.
`supply.capital`	the supply of capital.
`names.commodity`	names of commodities.
`names.agent`	names of agents.

Details

Given a 5×4 input-output table (e.g., see Zhang Xin, 2017, Table 8.6.1), this model calculates the corresponding general equilibrium. This input-output table contains 3 production sectors and one household. The household consumes products and supplies labor and capital.

Value

A general equilibrium which is a list with the following elements:

- D - the demand matrix, also called the input table. Wherein the benchmark prices are used.
- DV - the demand value matrix, also called the value input table. Wherein the current price is used.
- SV - the supply value matrix, also called the value output table. Wherein the current price is used.
- ... - some elements returned by the CGE::sdm function

`gemInputOutputTable_7_4` *A General Equilibrium Model based on a 7×4 (Standard) Input-Output Table*

Description

This is a general equilibrium model based on a 7×4 standard input-output table. There is no negative number in this standard input-output table, and both the input and output parts are 7×4 matrices. The standard input-output table consists of input and output parts with the same dimensions.

Usage

```
gemInputOutputTable_7_4(
  IT,
  OT,
  es.agri = 0,
```

```
  es.manu = 0,
  es.serv = 0,
  es.hh = 0,
  es.VA.agri = 0.25,
  es.VA.manu = 0.5,
  es.VA.serv = 0.8,
  ...
)
```

Arguments

IT	the input part of the input-output table in the base period (unit: trillion yuan).
OT	the output part of the input-output table in the base period (unit: trillion yuan).
es.agri, es.manu, es.serv	the elasticity of substitution between the intermediate input and the value-added input of the agriculture sector, manufacturing sector and service sector.
es.hh	the elasticity of substitution among products consumed by the household sector.
es.VA.agri, es.VA.manu, es.VA.serv	the elasticity of substitution between labor input and capital input of the agriculture sector, manufacturing sector and service sector.
...	arguments to be transferred to the function sdm of the package CGE.

Details

Given a 7×4 input-output table, this model calculates the corresponding general equilibrium. This input-output table contains 3 production sectors and 1 household. The household consumes products and supplies labor, capital, stock and tax receipt. Generally speaking, the value of the elasticity of substitution in this model should be between 0 and 1.

Value

A general equilibrium, which is a list with the following elements:

- p - the price vector with labor as numeraire.
- D - the demand matrix, also called the input table. Wherein the benchmark prices are used.
- DV - the demand value matrix, also called the value input table. Wherein the current price is used.
- SV - the supply value matrix, also called the value output table. Wherein the current price is used.
- value.added - the value-added of the three production sectors.
- dstl - the demand structure tree list of sectors.
- ... - some elements returned by the sdm2 function.

Examples

```

gemInputOutputTable_8_8 *A General Equilibrium Model based on an 8×8 Input-Output Table*

Description

This is a general equilibrium model based on a 8×8 input-output table.

Usage

```
gemInputOutputTable_8_8(
  IT,
  OT,
  es.agri = 0,
  es.manu = 0,
  es.serv = 0,
  es.CI = 0,
  es.FT = 0,
  es.VA.agri = 0.25,
  es.VA.manu = 0.5,
  es.VA.serv = 0.8,
  es.prodDM = 0.5,
```

```
  ...
)
```

Arguments

IT	the input part of the input-output table in the base period (unit: trillion yuan).
OT	the output part of the input-output table in the base period (unit: trillion yuan).
es.agri, es.manu, es.serv	the elasticity of substitution between the intermediate input and the value-added input of the agriculture sector, manufacturing sector and service sector.
es.CI	the elasticity of substitution among products used by the CI sector.
es.FT	the elasticity of substitution among exported products.
es.VA.agri, es.VA.manu, es.VA.serv	the elasticity of substitution between labor input and capital input of the agriculture sector, manufacturing sector and service sector.
es.prodDM	the elasticity of substitution between domestic product and imported product.
...	arguments to be transferred to the function sdm of the package CGE.

Details

Given an 8×8 input-output table, this model calculates the corresponding general equilibrium. This input-output table contains 3 production sectors, 1 consumption and (temporarily unproductive) investment sector (CI sector), 1 foreign trade sector importing agriculture goods, 1 foreign trade sector importing manufacturing goods, 1 foreign trade sector importing service, 1 foreign trade sector importing bond. There are 8 kinds of commodities (or subjects) in the table, i.e. agriculture product, manufacturing product, service, labor, capital goods, tax, dividend and bond of ROW (i.e. the rest of the world). The CI sector uses products and supplies labor, capital, stock and tax receipt. Generally speaking, the value of the elasticity of substitution in this model should be between 0 and 1.

Value

A general equilibrium, which is a list with the following elements:

- p - the price vector with labor as numeraire.
- D - the demand matrix, also called the input table. Wherein the benchmark prices are used.
- DV - the demand value matrix, also called the value input table. Wherein the current price is used.
- SV - the supply value matrix, also called the value output table. Wherein the current price is used.
- value.added - the value-added of the three production sectors.
- dstl - the demand structure tree list of sectors.
- ... - some elements returned by the CGE::sdm function

Examples

```
IT17 <- matrix(c(
  1.47, 6.47, 0.57, 2.99, 0.12 * 0.60 / (0.60 + 12.10 + 2.23 + 1.45),
  0.12 * 12.10 / (0.60 + 12.10 + 2.23 + 1.45),
  0.12 * 2.23 / (0.60 + 12.10 + 2.23 + 1.45),
  0.12 * 1.45 / (0.60 + 12.10 + 2.23 + 1.45),

  2.18, 76.32, 12.83, 43, 13.30 * 0.60 / (0.60 + 12.10 + 2.23 + 1.45),
  13.30 * 12.10 / (0.60 + 12.10 + 2.23 + 1.45),
  13.30 * 2.23 / (0.60 + 12.10 + 2.23 + 1.45),
  13.30 * 1.45 / (0.60 + 12.10 + 2.23 + 1.45),

  0.82, 19.47, 23.33, 34.88, 2.96 * 0.60 / (0.60 + 12.10 + 2.23 + 1.45),
  2.96 * 12.10 / (0.60 + 12.10 + 2.23 + 1.45),

`gemInputOutputTable_easy_5_4` *An Easy General Equilibrium Model based on a 5×4 Input-Output Table (see Zhang Xin, 2017, Table 8.6.1)*

Description

This is a general equilibrium model based on a 5×4 input-output table (see Zhang Xin, 2017, Table 8.6.1).

Usage

```
gemInputOutputTable_easy_5_4(
 IT = cbind(sector.agri = c(agri = 260, manu = 345, serv = 400, lab = 200, cap = 160),
    sector.manu = c(agri = 320, manu = 390, serv = 365, lab = 250, cap = 400),
  sector.serv = c(agri = 150, manu = 390, serv = 320, lab = 400, cap = 210), sector.hh
    = c(agri = 635, manu = 600, serv = 385, lab = 0, cap = 0)),
  supply.labor = 850,
  supply.capital = 770,
  es.agri = 0.2,
  es.manu = 0.3,
  es.serv = 0.1,
  es.VA.agri = 0.25,
  es.VA.manu = 0.5,
  es.VA.serv = 0.8
)
```

Arguments

`IT`	the input and consumption part of the input-output table.
`supply.labor`	the supply of labor.
`supply.capital`	the supply of capital.
`es.agri, es.manu, es.serv`	the elasticity of substitution between the intermediate input and the value-added input of the agriculture sector, manufacturing sector and service sector.
`es.VA.agri, es.VA.manu, es.VA.serv`	the elasticity of substitution between labor input and capital input of the agriculture sector, manufacturing sector and service sector.

Details

Given a 5×4 input-output table (e.g., see Zhang Xin, 2017, Table 8.6.1), this model calculates the corresponding general equilibrium. This input-output table contains 3 production sectors and one household. The household consumes products and supplies labor and capital.

Value

A general equilibrium, which is a list with the following elements:

- p - the price vector with labor as numeraire.
- D - the demand matrix, also called the input table. Wherein the benchmark prices are used.
- DV - the demand value matrix, also called the value input table. Wherein the current price is used.
- SV - the supply value matrix, also called the value output table. Wherein the current price is used.
- ... - some elements returned by the CGE::sdm function

Examples

```
sector.agri <- c(260, 345, 400, 200, 160)
sector.manu <- c(320, 390, 365, 250, 400)
sector.serv <- c(150, 390, 320, 400, 210)
sector.hh <- c(635, 600, 100, 0, 0)

IT <- cbind(sector.agri, sector.manu, sector.serv, sector.hh)
rownames(IT) <- c("agri", "manu", "serv", "lab", "cap")

ge <- gemInputOutputTable_easy_5_4(IT)

####
ge <- gemInputOutputTable_easy_5_4(supply.capital = 1870)
prop.table(ge$z[1:3])
```

---

gemInputOutputTable_Leontief_3_3

A Leontief-type General Equilibrium Model based on a 3×3 Input-Output Table

---

Description

Given a 3×3 input-output table (e.g., see Zhang Xin, 2017, Table 2.2.2), this model can be used to calculate the corresponding equilibrium. This input-output table contains two firms and one household. The household consumes products and supplies labor.

Usage

```
gemInputOutputTable_Leontief_3_3(
  input = matrix(c(200, 300, 100, 150, 320, 530, 250, 380, 0), 3, 3, TRUE),
  output = c(600, 1000, 630)
)
```

Arguments

input	the input matrix in the base period.
output	a vector consisting of the product outputs and labor supply in the base period.

Value

A general equilibrium, which is a list with the following elements:

- p - the price vector with labor as numeraire.
- D - the demand matrix, also called the input table. Wherein the benchmark prices are used.
- DV - the demand value matrix, also called the value input table. Wherein the current price is used.
- SV - the supply value matrix, also called the value output table. Wherein the current price is used.
- ... - some elements returned by the CGE::sdm function

Examples

```
x <- 75
gemInputOutputTable_Leontief_3_3(
  input = matrix(c(
    200, 300, 100,
    x, 320, 530,
    250, 380, 0
  ), 3, 3, TRUE),
  output = c(600, 1000, 630)
)
```

---

gemInputOutputTable_SCES_3_3

A SCES-type General Equilibrium Model based on an Input-Output Table.

Description

Given a 3×3 input-output table (e.g., see Zhang Xin, 2017, Table 2.2.2), this model can be used to calculate the corresponding equilibrium. This input-output table contains two firms and one household. The household consumes products and supplies labor.

Usage

```
gemInputOutputTable_SCES_3_3(
  input = matrix(c(200, 300, 100, 150, 320, 530, 250, 380, 0), 3, 3, TRUE),
  output = c(600, 1000, 630),
  es = 0
)
```

Arguments

input	the input matrix in the base period.
output	a vector consisting of the product outputs and labor supply in the base period.
es	a scalar, which is the elasticity of substitution between the inputs.

Value

A general equilibrium, which is a list with the following elements:

- p - the price vector with labor as numeraire.
- D - the demand matrix, also called the input table. Wherein the benchmark prices are used.
- DV - the demand value matrix, also called the value input table. Wherein the current price is used.
- SV - the supply value matrix, also called the value output table. Wherein the current price is used.
- ... - some elements returned by the CGE::sdm function

  ), 3, 3, TRUE),
  output = c(600, 1000, 630),
  es = 0.5
)
```

`gemInstantaneousEquilibriumPath_StickyDecisions` *Some Examples of Instantaneous Equilibrium Paths with Sticky Decisions*

Description

Some examples of instantaneous equilibrium paths with sticky decisions of a firm, that is, the firm sluggishly adjusts its technology in response to price changes.

Under the assumption of (complete) rationality, economic agents will make decisions that are most beneficial to them based on the information they have. If the information does not change, then the decision will not change. However, under the assumption of bounded rationality, the decisions made by economic agents may not be optimal. They may follow some simple rules-of-thumb, and might adjust their previous decisions sluggishly according to the changes in information, even though they have the capability to adjust flexibly, so that the new decisions are better than the old ones under the new information. Hence the current decision is not necessarily the optimal decision. Even if the information does not change, it is still possible for agents to make further improvements to this decision in the next period. It can also be said that in this case, the decision maker's decision is sticky, that is, it only makes limited improvements to the previous decision based on new information, rather than directly adjusting to the optimal decision.

Usage

```
gemInstantaneousEquilibriumPath_StickyDecisions(...)
```

Arguments

`...`	arguments to be passed to the function sdm2.

See Also

`gemIntertemporal_1_2` *An Example of a 1-by-2 Intertemporal Equilibrium Model*

Description

An example of an intertemporal equilibrium model with one type of commodity (i.e., product) and two types of agents (i.e., a firm with an AK production function and a consumer).

Usage

```
gemIntertemporal_1_2(...)
```

Arguments

`...`	arguments to be passed to the function sdm2.

Examples

```
eis <- 0.5 # the elasticity of intertemporal substitution of the consumer
Gamma.beta <- 0.97 # the subjective discount factor of the consumer
alphaK <- 1.1 # the parameter of the AK production function

np <- 5 # the number of economic periods
```

```
n <- np # the number of commodity kinds
m <- np # the number of agent kinds

names.commodity <- paste0("prod", 1:np)
names.agent <- c(paste0("firm", 1:(np - 1)), "consumer")

# the exogenous supply matrix.
S0Exg <- matrix(NA, n, m, dimnames = list(names.commodity, names.agent))
S0Exg[paste0("prod", 1:np), "consumer"] <- 100

# the output coefficient matrix.
B <- matrix(0, n, m, dimnames = list(names.commodity, names.agent))
for (k in 1:(np - 1)) {
  B[paste0("prod", k + 1), paste0("firm", k)] <- 1
}

dstl.firm <- list()
for (k in 1:(np - 1)) {
  dstl.firm[[k]] <- node_new(
    "prod",
    type = "Leontief",
    a = 1 / alphaK,
    paste0("prod", k)
  )
}

dst.consumer <- node_new(

```

gemIntertemporal_2_2 *Some Examples of a 2-by-2 Intertemporal Equilibrium Model*

Description

Some examples of an intertemporal equilibrium model with two types of commodities and two types of agents.

In these examples, there is an np-period-lived consumer maximizing intertemporal utility, and there is a type of firm which produces from period 1 to np-1. There are two types of commodities, i.e. product and labor. Assume the consumer has some product in the first period. That is, the product supply in the first period is an exogenous variable.

Usage

```
gemIntertemporal_2_2(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
#### an example with a Cobb-Douglas intertemporal utility function
np <- 5 # the number of economic periods
y1 <- 150 # the initial product supply

n <- 2 * np - 1 # the number of commodity kinds
m <- np # the number of agent kinds

```

`gemIntertemporal_3_3` *Some Examples of Intertemporal Models with One Consumer and Two Types of Firms*

Description

Some examples of intertemporal models with one consumer and two types of firms. There are three types of commodities (i.e. corn, iron and labor). The consumer may consume corn and iron in each period, and may have a nested intertemporal utility function.

Usage

```
gemIntertemporal_3_3(...)
```

Arguments

`...`	arguments to be passed to the function sdm2.

`gemIntertemporal_5_5` *Some Intertemporal (Timeline and Time-circle) Models with Land, Two Consumers, and Three Types of Firms*

Description

Some intertemporal (timeline and time-circle) models with two consumers (i.e. a laborer and a landowner) and three types of firms (i.e. wheat producers, iron producers and iron leaser). Here the iron leasing firm is actually a quasi-firm, which does not require primary factors such as labor and land in its production process. There are four commodities in the model, namely wheat, iron, iron leased out as a capital good, labor and land.

Usage

```
gemIntertemporal_5_5(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
#### a timeline model.
np <- 15 # the number of economic periods
gr <- 0 # the growth rate in the steady state equilibrium
eis <- 1 # the elasticity of intertemporal substitution  of consumers
Gamma.beta <- 0.97 # the subjective discount factor of consumers
last.beta.laborer <- 0
last.beta.landowner <- 0
depreciation.rate <- 0.06

gemIntertemporal_AdValoremClaim
Some Intertemporal Models with Ad Valorem Claim

Description

Some intertemporal models with ad valorem claim. Ad valorem claims may be equities, bonds, ad valorem taxation rights (ad valorem tax receipt), fiat money etc, which can be treated in the same way in models.

Usage

```
gemIntertemporal_AdValoremClaim(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
#### a model with tax.
np <- 5 # the number of economic periods
gr.lab <- 0.03 # the growth rate of the labor supply
tax.rate <- 0.25

n <- 2 * np + 1 # the number of commodity kinds
m <- np + 1 # the number of agent kinds

names.commodity <- c(paste0("prod", 1:np), paste0("lab", 1:np), "tax receipt")
names.agent <- c(paste0("firm", 1:(np - 1)), "laborer", "government")

# the exogenous supply matrix.
S0Exg <- matrix(NA, n, m, dimnames = list(names.commodity, names.agent))
S0Exg[paste0("lab", 1:np), "laborer"] <- 100 * (1 + gr.lab)^(0:(np - 1)) # the labor supply
S0Exg["prod1", "laborer"] <- 10 # the product supply in the first period
S0Exg["tax receipt", "government"] <- np * 100 # the supply of tax receipt (i.e. ad valorem claim)

# the output coefficient matrix.
B <- matrix(0, n, m, dimnames = list(names.commodity, names.agent))

gemIntertemporal_Bank_1_2 *Some Examples of an Intertemporal Model with a Consumer and a Type of Bank*

Description

Some examples of an intertemporal model with a consumer and a type of bank. These models can be used to solve some intertemporal savings problems. Below is an example.

A np-period-lived consumer has some payoff (or cash, exhaustible resource etc.) in each period. In each period the consumer can use payoff for consumption or save payoff into bank. The interest rate is given. The consumer has a SCES intertemporal utility function and attempts to maximize intertemporal utility by saving.

Usage

```
gemIntertemporal_Bank_1_2(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
#### an example with a 5-period-lived consumer
np <- 5 # the number of economic periods

interest.rate <- 0.1

n <- np # the number of commodity kinds
m <- np # the number of agent kinds

names.commodity <- paste0("payoff", 1:np)

gemIntertemporal_Dividend_TechnologicalProgress

The Identical Steady-state Equilibrium: Four Models Illustrating Dividend and Technological Progress

---

Description

Four models with labor-saving technological progress are presented to illustrate dividend, which have the same steady-state equilibrium.

These models are as follows: (1) a real timeline model with head-tail adjustment; (2) a financial timeline model with dividend and head-tail adjustment; (3) a financial sequential model with dividend; (4) a financial time-circle model with dividend.

Usage

```
gemIntertemporal_Dividend_TechnologicalProgress(...)
```

Arguments

...	arguments to be passed to the function sdm2.

gemIntertemporal_EndogenousEquilibriumInterestRate

An Example Illustrating Endogenous Equilibrium Interest Rates in a (Timeline) Transitional Equilibrium Path

---

Description

This example illustrates (endogenous) equilibrium primitive interest rates in a transitional equilibrium path, which is an intertemporal path distinct from a steady-state equilibrium. The interest rate calculated here is adjusted from the nominal interest rate based on the growth rate of the money supply, which is equal to the nominal interest rate when the money stock remains unchanged. We refer to this kind of interest rate as the primitive interest rate, which usually differs from the real interest rate obtained by adjusting the nominal rate based on the inflation rate.

There are three types of economic agents in the model: firms, a laborer, and a money owner. Suppose the laborer and the money owner need to use money to buy products, and firms need to use money to buy products and labor. Formally, the money owner borrows money from himself and pays interest to himself.

Usage

```
gemIntertemporal_EndogenousEquilibriumInterestRate(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
vm <- 1 # the velocity of money
eis <- 0.8 # the elasticity of intertemporal substitution
Gamma.beta <- 0.8 # the subjective discount factor
gr <- 0 # the growth rate
np <- 20 # the number of economic periods

f <- function(ir = rep(0.25, np - 1), return.ge = FALSE,
              y1 = 10, # the product supply in the first period
              alpha.firm = rep(2, np - 1) # the efficiency parameters of firms

`gemIntertemporal_Money_Dividend_Example7.5.1`
The Identical Steady-state Equilibrium: Three Models with Money and Dividend

---

Description

Three steady-state-identical models with money and dividend as follows: (1) a sequential model (Li, 2019, example 7.5); (2) a time-circle model; (3) a timeline model with head-tail adjustment.

Stocks, fiat currencies, bonds, and taxes, etc. can be collectively referred to as ad valorem claims. Sometimes we do not need to differentiate between these financial instruments when modeling. Furthermore, sometimes we do not need to consider which period these financial instruments belong to.

Usage

```
gemIntertemporal_Money_Dividend_Example7.5.1(...)
```

Arguments

...	arguments to be passed to the function sdm2.

`gemIntertemporal_PublicFirm` *Some Examples of Intertemporal (Timeline) Models with Production and Public Firms*

Description

Some examples of intertemporal (timeline) models with production and public firms. A public producer is akin to a consumer with an infinite lifespan. The public producer owns the products it

manufactures. In each period, it exchanges the products it has produced for the inputs required for production. In intertemporal models, a public producer can be treated as multiple public firms that each only produces for a single period. Each public firm hands over its products to the public firm of the next period, which in turn uses these products for trading.

Usage

```
gemIntertemporal_PublicFirm(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
np <- 15 # the number of economic periods, firms.
gr <- 0  # the growth rate of the labor supply
eis <- 0.5 # the elasticity of intertemporal substitution
Gamma.beta <- 0.9 # the subjective discount factor

`gemIntertemporal_TimeCircle_2_2` *Some Examples of a 2-by-2 Time Circle Equilibrium Model*

Description

Some examples of a 2-by-2 (intertemporal) time circle equilibrium model. In a time circle model, the economy borrows some resources from the outside in the beginning, and will repay it after the economy ends.

In these examples, there is an np-period-lived consumer maximizing intertemporal utility, and there is a type of firm which produces from period 1 to np. There are two commodities, i.e. product and labor. Suppose the firm can borrow some product from outside in the first period and return them in the (np+1)-th period. And the supply of product in the first period can be regarded as the output of the firm in the (np+1)-th period. Hence the product supply in the first period is an endogenous variable. Suppose that the amount returned is zeta times the amount borrowed.

Usage

```
gemIntertemporal_TimeCircle_2_2(...)
```

Arguments

`gemIntertemporal_TimeCircle_Bank_1_2` *Some Examples of a Time Circle Model with a Consumer and a Type of Bank*

Description

Some examples of a time circle model with a consumer and a type of bank. These models can be used to solve some intertemporal savings problems.

In these example, an np-period-lived consumer gets some payoff (or cash, exhaustible resource etc.) in each period. In each period the consumer can use payoff for consumption, save payoff into bank or get a loan from the bank. The interest rate is given. The consumer has a CES intertemporal utility function and attempts to maximize intertemporal utility by saving and borrowing.

Usage

```
gemIntertemporal_TimeCircle_Bank_1_2(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
#### an example with a 5-period-lived consumer (see Zhang, 2008, section 1.3)
np <- 5 # the number of economic periods
interest.rate <- 0.1
zeta <- (1 + interest.rate)^np # the ratio of repayments to loans

`gemIntertemporal_TimeCircle_Stochastic_2_2`
Some 2-by-2 Time Circle Models with Uncertainty

Description

Some time circle models with uncertainty. In these models, there is a consumer who will live for two periods and has a von Neumann-Morgenstern expected utility function. There is one natural state

in the first period, and two natural states in the second period. In the economy, there are two types of commodities: product and labor. In the first period, the economy can borrow a certain amount of product from an external source, such as a bank, and repay it after the economic operation is complete. The amount of product to be repaid is zeta times the amount borrowed. zeta is an exogenous variable.

Usage

```
gemIntertemporal_TimeCircle_Stochastic_2_2(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
#### Assume that the consumer supplies labor only in the first period,
## and the firm produces only in the first period.
zeta <- 1.25 # the ratio of repayments to loans

gemMoney_3_2 *A General Equilibrium Model with Money*

Description

A general equilibrium model with money as a medium of exchange and a means of payment.

Usage

```
gemMoney_3_2(
  dstl,
  supply.labor = 100,
  supply.money = 300,
  names.commodity = c("product", "labor", "money"),
  names.agent = c("firm", "household"),
  ...
)
```

Arguments

dstl	the demand structure tree list.
supply.labor	the supply of labor.
supply.money	the supply of money.
names.commodity	names of commodities.

names.agent	names of agents.
...	arguments to be to be passed to the function sdm2.

Details

A general equilibrium model with 3 commodities (i.e. product, labor, and money) and 2 agents (i.e. a firm and a household). To produce, the firm needs product, labor and money. The household only consumes the product. But money is also needed to buy the product. The household supplies labor and money.

In the calculation results, the price of the currency is the interest per unit of currency (i.e., the rental price). It should be noted that the unit of currency can be arbitrarily selected. For example, a unit of currency may be two dollars or ten dollars. The rental price divided by the interest rate is the asset price of 1 unit of the currency.

Value

A general equilibrium (see sdm2)

Examples

```
#### Leontief-type firm
interest.rate <- 0.25
vm <- 1 # the velocity of money

dst.Leontief.firm <- node_new("output",
  type = "FIN", rate = c(1, interest.rate / vm),
  "cc1", "money"
)
node_set(dst.Leontief.firm, "cc1",
  type = "Leontief", a = c(0.6, 0.2),
  "product", "labor"
)

dst.household <- node_new("utility",
  type = "FIN", rate = c(1, interest.rate / vm),
  "product", "money"
)

dstl.Leontief <- list(dst.Leontief.firm, dst.household)

ge.Leontief <- gemMoney_3_2(dstl.Leontief)
ge.Leontief$p

## SCES-type firm
dst.SCES.firm <- Clone(dst.Leontief.firm)
node_set(dst.SCES.firm, "cc1",
  type = "SCES", alpha = 1, beta = c(0.6, 0.2),
  es = 0 # es is the elasticity of substitution.
)
```

```
node_plot(dst.SCES.firm, TRUE)

dstl.SCES <- list(dst.SCES.firm, dst.household)

ge.SCES <- gemMoney_3_2(dstl.SCES)
ge.SCES$p
p.money <- ge.SCES$p
p.money["money"] <- p.money["money"] / interest.rate
p.money <- p.money / p.money["money"] # prices in terms of the asset price of the currency
p.money

## The price of money is the interest rate.
## The other prices are in terms of the asset price of the currency.
gemMoney_3_2(dstl.SCES,
             numeraire = c("money" = interest.rate)
)
```

`gemMoney_3_3` *Some 3-by-3 General Equilibrium Models with Money and Exogenous Interest Rate*

Description

Some 3-by-3 general equilibrium models with money as a medium of exchange and a means of payment. Here, the interest rate is an exogenous variable.

In these examples, the price of money refers to its rental price, which is the interest amount generated per unit of money. The value of a unit of currency (i.e., its selling price or asset price) is its rental price divided by the interest rate. When the rental price of money equals the interest rate, the value of the currency equals 1, which implies that money is used as the numeraire (i.e. the unit of account).

Usage

```
gemMoney_3_3(...)
```

Arguments

...	arguments to be passed to the function sdm2.

`gemNonrivalry_Uncongestiblity` *Some Examples Illustrating Uncongestible Non-rival Goods*

Description

Some examples illustrating (uncongestible) non-rival goods (or services), Lindahl prices and the uniform price. In general equilibrium models, non-rival services can be regarded as personalized services, which are joint products of a production process (see Mas-Colell, Whinston, and Green, 1995, section 16.G).

Usage

```
gemNonrivalry_Uncongestiblity(...)
```

Arguments

...	arguments to be passed to the function sdm2.

References

Mas-Colell, Andreu and Whinston, Michael Dennis and Green, Jerry R. (1995, ISBN: 0195073401) Microeconomic Theory. Oxford University Press (New York).

Examples

```
## The firm supplies non-rival services.
dst.firm <- node_new(
  "non-rival services",
  type = "Leontief", a = 1,
  "labor"
)

dst.consumer1 <- node_new(
  "util",
  type = "SCES", es = 1, # es = 0
  alpha = 1, beta = c(0.75, 0.25),
  "serv1", "labor"
)

dst.consumer2 <- node_new(
  "util",
  type = "SCES", es = 1, # es = 0
  alpha = 1, beta = c(0.5, 0.5),
  "serv2", "labor"
)

ge <- sdm2(

gemOLGF_OneFirm *Overlapping Generations Financial Sequential Models with One Firm*

Description

Some examples of overlapping generations financial sequential models with one firm.

When there is a population growth, we will take the security-split assumption (see gemOLGF_PureExchange).

Usage

```
gemOLGF_OneFirm(...)
```

Arguments

...	arguments to be passed to the function sdm2.

gemOLGF_PureExchange *Overlapping Generations Financial Sequential Models for Pure Exchange Economies*

Description

Some examples of overlapping generations sequential models with financial instrument for pure exchange economies.

In these examples, there is a financial instrument (namely security) which serves as saving means and can be regarded as money, the shares of a firm, etc. Consumers use this security for saving, and this is the only use of the security. As Samuelson (1958) wrote, society by using money (i.e. security) will go from the non-optimal configuration to the optimal configuration.

Here financial demand structure trees are used, which contain financial nodes. A financial demand structure tree reflects the demand structure of a consumer who has a demand for financial instruments. Although CD-type nodes can be used instead of financial-type nodes in the consumer's demand structure tree, the use of financial-type nodes will make the demand structure tree easier to understand.

When there is a population growth, we will take the security-split assumption. That is, assume that in each period the security will be split just like share split, and the growth rate of the quantity of the security is equal to the growth rate of the population. Obviously, this assumption will not affect the calculation results essentially. And with this assumption, the equilibrium price vector can keep constant in each period, and the nominal rates of profit and interest will equal the real rates of profit and interest (i.e. the population growth rate). In contrast, in the time circle model the nominal rates of profit and interest equal zero and the real rates of profit and interest equal the population growth rate.

Usage

```
gemOLGF_PureExchange(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Note

As can be seen from the first example below, in a pure exchange economy with two-period-lived consumers, if age1 (i.e. young) has one unit of labor and age2 (i.e. old) does not, then the optimal allocation can be obtained by introducing securities. Here it is assumed that each consumer consumes one unit of labor in total.

However, if age2 (i.e. adult) has one unit of labor and age1 (i.e. child) does not, we cannot get the optimal allocation by introducing securities. So we need the family system.

gemOLG_Basic *Some Examples of Basic (Timeline) OLG Models with Production*

Description

Some examples of basic (timeline) OLG models with production. In these models there are two types of commodities (i.e., labor and product) and two types of economic agents (i.e., laborers and firms). Laborers (i.e., consumers) live for two or three periods. These models can be easily extended to include more types of commodities, consumers and firms, and to allow consumers to live for more periods.

Usage

```
gemOLG_Basic(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
## When beta.consumer[1]==0, beta.consumer[2:3]>0, labor.first[1]>0, labor.first[2:3]==0,
## this model is actually the Diamond model. However, the division of periods is
## slightly different from the Diamond model.

gemOLG_Land_4_3 *An Overlapping Generations Model with Land*

Description

Some examples of an overlapping generations model with land.

Usage

```
gemOLG_Land_4_3(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Details

In this model, consumers live for two periods. Age2 owns a unit of land and age1 owns a unit of labor. Here the land use rights and land ownership are regarded as two commodities. Age2 gets land rent by selling land use rights to the firm. Then land ownership is sold to age1. Age1 saves by purchasing land ownership.

Here, the ratio of land rent to wage (denoted as xi) is determined by the production function. No matter what the saving rate of age1 is, and at what price the land ownership is transferred to age1, the consumption ratio of age2 and age1 will not be less than xi.

When the consumer's intertemporal utility function is min(c1, c2), the intertemporal substitution elasticity is 0, and each consumer desires the same amount of consumption in the two periods. It can also be assumed that the consumer's intertemporal substitution elasticity is close to 0 rather than exactly zero.

If xi>1, then this economy will inevitably have efficiency loss (dynamic inefficiency). In this case, in order to achieve the optimal allocation, not only age2 should give land to age1 for free, but age2 also needs to distribute part of the land rent to age1. However, age2 has no incentive to do so.

`gemOLG_PrivateFirm` *Overlapping Generations Models with Private Firm*

Description

Some examples of overlapping generations models with private firm. A public (i.e. publicly held) firm exists permanently and operates independently. If a public firm ownership transfers between generations, this transfer will be done through the exchange of shares. In contrast, here a private firm is established by a consumer and only runs before she retires.

In the first example, there are some two-period-lived consumers and a private firm. Suppose age1 has a unit of labor and age2 has not. In each period age1 establishes a private firm and the firm gets some labor as investment from age1 and will sell it in the market to buy some inputs for production. In the next period, age2 (i.e. age1 in the previous period) gets the output of the firm. Age2 consumes product and labor (i.e. service). Hence age1 and the firm can sell labor to age2 and buy product from age2.

In the second example with three-period-lived consumers, there are two private firms (i.e. firm1 and firm2). In each period age1 establishes a new firm1 and age2 establishes a new firm2. Firm1 gets some labor as investment from age1 and firm2 gets some product and labor as investment from age2. The output of firm1 belongs to age2 in the next period and the output of firm2 belongs to age3 in the next period. In each period age2 (i.e. age1 in the previous period) takes away the output of firm1 and age3 (i.e. age2 in the previous period) takes away the output of firm2.

Usage

```
gemOLG_PrivateFirm(...)
```

Arguments

`gemOLG_PureExchange` *The Basic Overlapping Generations Pure Exchange Model (see Samuelson, 1958)*

Description

This is the basic overlapping generations pure exchange model.

Usage

```
gemOLG_PureExchange(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Details

As Samuelson (1958) wrote, break each life up into thirds. Agents get 50 units of payoff in period 1 and 50 units in period 2; in period 3 they retire and get nothing. Suppose there are three agents in each period, namely age1, age2 and age3. In the next period, the present age1 will become age2, the present age2 will become age3, the present age3 will disappear and a new age1 will appear. Let c1, c2 and c3 denote the consumption of an agent in each period. Suppose the utility function is (c1 * c2 * c3)^(1 / 3), which is actually the same as log(c1) + log(c2) + log(c3). In each period, age1 and age2 will exchange their payoffs of the present period and the next period. Age2 will sell some present payoff and buy some future payoff as pension, and for age1, it's the opposite. Age3 simply receives the pension and need not take part in the exchange. Hence only two agents participate in the pure exchange economy. In the exchange process, the utility function of age1 is c1^(1 / 3) * x2^(2 / 3), wherein x2 is the revenue of the next period, and the utility function of age2 is c2^(1 / 2) * c3^(1 / 2).

Note

We can also suppose only age2 gets payoff and age1 does not.

`gemOLG_PureExchange_Bank` *Overlapping Generations Pure Exchange Models with Bank*

Description

Some examples of overlapping generations pure exchange models with bank. Under a pay-as-you-go system, banks may only redistribute payoffs among consumers in each period. This is, in each period a bank can get a part of payoff of age1 and pay it to age2 immediately. From the consumer's point of view, the bank converts the current period's payoff into the next period's payoff. Each consumer only transacts with the bank, and she can assume that there are no other consumers.

Usage

```
gemOLG_PureExchange_Bank(...)
```

Arguments

...	arguments to be passed to the function sdm2.

`gemOLG_StochasticSequential_3_3`
A 3-by-3 OLG Stochastic Sequential General Equilibrium Model

Description

A 3-by-3 OLG stochastic sequential general equilibrium model. There are two-period lived consumers and a type of firm. There are three types of commodities, i.e. product, labor and security (i.e. paper asset, store of value).

In each period there are a young (i.e. age1), an old (i.e. age2) and a firm. The young supplies a unit of labor and the old supplies a unit of security.

Consumers only consume products. The young buys the security to save.

The firm inputs labor to produce the product. Productivity is random. The amount of labor required to produce 1 unit of product is equal to 0.1 or 0.2, both of which occur with equal probability.

All labor is used in production. Therefore, it can be known that the product output in each period (that is, the product supply in the next period) is equal to 10 or 5, that is to say, there are two natural states with equal probability of occurrence in each period: good state and bad state. The states are denoted as a and b, respectively. There are then four cases of natural states experienced by a consumer in two periods: aa, bb, ab and ba.

Take the product as numeraire. The ratio of the security price in the latter period to the previous period of the two periods is the gross rate of return. The gross rates of return on the savings of the young in the four cases is denoted as Raa, Rbb, Rab and Rba, respectively.

The utility function of the young is -0.5*x1^-1 - 0.25*x2^-1 - 0.25*x3^-1, where x1, x2 and x3 are the (expected) consumption in the current period and the next two natural states, respectively. It can be seen that the intertemporal substitution elasticity and the inter-natural-state substitution elasticity in the utility function are both 0.5, that is, the relative risk aversion coefficient is 2.

In each period, the young determines the saving rate based on the expected gross rates of return on the security and the utility function.

In each period the young adopts the following anticipation method for the gross rate of return of the savings: First, determine the two types of gross rates of return (Raa, Rab or Rbb, Rba) that need to be predicted according to the current state. Both interest rates are then forecasted using the adaptive expectation method.

A spot market clearing path (alias instantaneous equilibrium path) and a disequilibrium path will be calculated below. The spot market clearing path will converge to the stochastic equilibrium consisting of two equilibrium states, and the disequilibrium paths not.

Usage

```
gemOLG_StochasticSequential_3_3(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
# a function to find the optimal saving rate given the expected gross rates of return.

gemOLG_TimeCircle *Time-Circle Models (Closed Loop Overlapping Generations Models)*

Description

Some examples of time-circle models, which usually contain overlapping generations. When we connect together the head and tail of time of a dynamic model, we get a time-circle model which treats time as a circle of finite length instead of a straight line of infinite length. The (discounted) output of the final period will enter the utility function and the production function of the first period, which implies the influence mechanism of the past on the present is just like the influence mechanism of the present on the future. A time-circle OLG model may be called a reincarnation model.

In a time-circle model, time can be thought of as having no beginning and no end. And we can assume all souls meet in a single market (see Shell, 1971), or there are implicit financial instruments that facilitate transactions between adjacent generations.

As in the Arrow–Debreu approach, in the following examples with production, we assume that firms operate independently and are not owned by consumers. That is, there is no explicit property of firms as the firms do not make pure profit at equilibrium (constant return to scale) (see de la Croix and Michel, 2002, page 292).

Usage

```
gemOLG_TimeCircle(...)
```

Arguments

...	arguments to be passed to the function sdm2.

`gemQuasilinearPureExchange_2_2` *A Pure Exchange Economy with a Quasilinear Utility Function*

Description

An example of a pure exchange economy with a quasilinear utility function (Karaivanov, see the reference).

Usage

```
gemQuasilinearPureExchange_2_2(
  A,
  Endowment = matrix(c(3, 4, 7, 0), 2, 2, TRUE),
  policy = NULL
)
```

Arguments

`A`	a demand structure tree list, a demand coefficient 2-by-2 matrix (alias demand structure matrix) or a function A(state) which returns a 2-by-2 matrix (see `sdm2`).
`Endowment`	a 2-by-2 matrix.
`policy`	a policy function (see `sdm2`).

Details

Suppose there are only two goods (bananas and fish) and 2 consumers (Annie and Ben) in an exchange economy. Annie has a utility function x_1^(1/3) * x_2^(2/3) where x_1 is the amount of fish she eats and x_2 is the amount of bananas she eats. Annie has an endowment of 3 kilos of fish and 7 bananas. Ben has a utility function x_1 + 1.5 * log(x_2) and endowments of 4 kilos of fish and 0 bananas. Assume the price of bananas is 1. See the reference for more details.

Value

A general equilibrium.

References

http://www.sfu.ca/~akaraiva/CE_example.pdf

Examples

```
demand_consumer2 <- function(w, p) {
  QL_demand(w = w, p = p, alpha = 1.5, type = "log")
}

A <- function(state) {
  a1 <- CD_A(1, rbind(1 / 3, 2 / 3), state$p)
  a2 <- demand_consumer2(state$w[2], state$p)
  cbind(a1, a2)
}

gemResearchDevelopmentIntensity

Some Examples of Spot Market Clearing Paths Illustrating Research and Development Intensity

---

Description

Some examples of spot market clearing paths (alias instantaneous equilibrium paths) illustrating R&D intensity. R&D intensity of a firm is the ratio of expenditures by the firm on R&D to the firm's sales.

Usage

```
gemResearchDevelopmentIntensity(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Details

The first example contains two kinds of commodities (namely product and labor) and three economic agents (namely a firm, a R&D center of the firm and a laborer). Since the R&D center does not produce products, the R&D center is regarded as a consumer-type agent in the model. The utility level of the R&D center (that is, the R&D level) will affect the technological progress rate of the firm. In the model, the firm allocates part of its output to the R&D centers for sale according to a given R&D intensity, which is equivalent to allocating part of the firm's sales revenue to the R&D center. At first, the economy is set in steady-state equilibrium without R&D activity. R&D activities begin in the fifth period.

Value

A spot market clearing path.

Examples

```
#### a 2-by-3 example.
RDIntensity <- 0.3
RDEffectivenessCoefficient <- 0.001

gemRobinson_3_2 *A Robinson Crusoe Economy*

Description

Compute the general equilibrium of a Robinson Crusoe economy.

Usage

```
gemRobinson_3_2(dstl, endowment)
```

Arguments

dstl	the demand structure tree list.
endowment	the endowment 3-vector. The endowment of the product is a non-negative number. The endowments of labor and land are positive numbers.

Details

A general equilibrium model with 3 commodities (i.e. product, labor, and land) and 2 agents (i.e. a firm and a consumer). The numeraire is labor.

Value

A general equilibrium.

gemstEndogenousLaborSupply_2_2
A General Equilibrium Model with Endogenous Labor Supply

Description

This is an example of the spot market clearing path (alias instantaneous equilibrium path) with endogenous labor supply. Assume that as the level of utility increases, laborer will purchase or receive more education and training, resulting in an increase in human capital, which can be regarded as an increase in labor supply. That is to say, the utility level as an endogenous variable will affect the supply of labor. Therefore, labor supply becomes an endogenous variable.

Usage

```
gemstEndogenousLaborSupply_2_2(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
f <- function(z0 = c(20, 1)) {
  ge <- sdm2(
    A = function(state) {
      a.firm <- CD_A(alpha = 5, Beta = c(0.5, 0.5), p = state$p)
      a.consumer <- c(1, 0)
      cbind(a.firm, a.consumer)
    },
    B = matrix(c(
      1, 0,
      0, 0
    ), 2, 2, TRUE),
    S0Exg = matrix(c(
      NA, NA,
      NA, 1
    ), 2, 2, TRUE),
    names.commodity = c("prod", "lab"),
    names.agent = c("firm", "consumer"),
    numeraire = "lab",
    z0 = z0,
    ts = TRUE,
    policy = list(
      function(state) {
        state$S[2, 2] <- structural_function(state$last.z[2], c(6.5, 7), 1, 2)
        state
      },
      policyMarketClearingPrice
    ),
    numberOfPeriods = 20,
```

```
    maxIteration = 1
  )
  matplot(ge$ts.z, type = "o", pch = 20)
  print(ge$z)
  print(ge$S)
}

f()

f(c(10,1))
```

---

gemstEndogenousProductionFunction_2_2 *A General Equilibrium Model with Endogenous Production Function*

Description

This is an example of the spot market clearing path (alias instantaneous equilibrium path) with an endogenous production function. The parameter of the production function will change with the output level.

To deal with locally or globally increasing returns to scale, we can simply use an endogenous CES-type production function instead of a production function with a more complex form.

Usage

```
gemstEndogenousProductionFunction_2_2(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
dst.firm <- node_new(
  "output",
  type = "CD", alpha = 5, beta = c(0.5, 0.5),
  "prod", "lab"
)

dst.consumer <- node_new(
  "util",
  type = "Leontief", a = 1,
  "prod"

`gemstEndogenousUtilityFunction`
Some General Equilibrium Models with Endogenous Utility Function

---

Description

Some examples of the spot market clearing path (alias instantaneous equilibrium path) with an endogenous utility function. The parameters of the utility function will change with the utility level.

To deal with non-homothetic preferences, we can simply use an endogenous CES-type utility function instead of a utility function with a more complex form.

Usage

```
gemstEndogenousUtilityFunction(...)
```

Arguments

`...`	arguments to be passed to the function sdm2.

Examples

```
#### a 2-by-2 example

`gemstStructuralMultipleEquilibria_2_2` *Structural Multiple Equilibria and Structural Transition Policy*

Description

Some examples of structural multiple equilibria and structural transition policy. In these examples it is assumed that the firm has a structural production function (see Li, Fu, 2020), e.g.

structural_function(last.output, c(0.3, 0.4), 1, 2) * x1^0.35 * x2^0.65

wherein last.output is the output of the firm in the previous period.

Usage

```
gemstStructuralMultipleEquilibria_2_2(...)
```

Arguments

`...`	arguments to be passed to the function sdm2.

gemTax_5_4 *A General Equilibrium Model with Tax (see Cardenete et al., 2012).*

Description

A general equilibrium model with tax (see chapter 4, Cardenete et al., 2012), wherein there are 5 commodities (i.e. product 1, product 2, labor, capital goods, and tax receipt) and 4 agents (i.e. 2 firms and 2 consumers).

Usage

```
gemTax_5_4(
  dstl,
  names.commodity = c("prod1", "prod2", "lab", "cap", "tax"),
  names.agent = c("taxed.firm1", "taxed.firm2", "consumer1", "consumer2"),
  delta = 1,
  supply.lab.consumer1 = 30,
  supply.cap.consumer1 = 20,
  supply.lab.consumer2 = 20,
  supply.cap.consumer2 = 5,
```

```
  policy.tax = NULL
)
```

Arguments

dstl	the demand structure tree list.
names.commodity	names of commodities.
names.agent	names of agents.
delta	the proportion of tax revenue allocated to consumer 1. 1-delta is the proportion of tax revenue allocated to consumer 2.
supply.lab.consumer1	the labor supply of consumer 1.
supply.cap.consumer1	the capital supply of consumer 1.
supply.lab.consumer2	the labor supply of consumer 2.
supply.cap.consumer2	the capital supply of consumer 2.
policy.tax	a tax policy function (see sdm2).

Value

A general equilibrium (see sdm2), wherein labor is the numeraire.

`gemTax_QuasilinearPreference_4_4` *A General Equilibrium Model with Tax and Quasilinear Utility Functions.*

Description

This model is essentially a pure exchange economy. The model contains 4 types of commodities (i.e. corn, iron, taxed iron and tax payment receipts) and 4 agents (i.e. consumer 1, consumer 2, a

firm and the government). Consumer 1 has corn and the utility function is x1 + beta1 * (alpha1 * x3 - 0.5 * x3^2) wherein x1 is corn and x3 is taxed iron. Consumer 2 has iron and the utility function is x1 + beta2 * (alpha2 * x2 - 0.5 * x2^2) wherein x1 is corn and x2 is iron. Consumer 1 (i.e. the iron demander) wants to buy iron from consumer 2 (i.e. the iron supplier) and the government will tax the transaction. The firm (i.e. a tax agency) inputs iron and tax payment receipts (similar to tax stamp) to output taxed iron, and due to government taxation requirements consumer 1 have to buy taxed iron from the firm and consumer 2 have to sell iron through the firm. Government has tax payment receipts and the utility function is x1.

Usage

```
gemTax_QuasilinearPreference_4_4(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Examples

```
tax.rate <- 1

beta1 <- 0.05

gemTemporaryEquilibriumPath

Some Examples of Temporary Equilibrium Paths

Description

Some examples of temporary equilibrium paths. The temporary equilibrium path consists of a series of temporary equilibria. Each temporary equilibrium achieves market clearing, and these markets may include futures markets in addition to spot markets. An instantaneous equilibrium path is a temporary equilibrium path that only includes spot markets.

Usage

```
gemTemporaryEquilibriumPath(...)
```

Arguments

...	arguments to be passed to the function sdm2.

References

gemTwoCountryPureExchange_Bond *Some Examples of Two-Country Pure Exchange Economy with Bond*

Description

Some general equilibrium examples of two-country pure exchange economy with bond.

Usage

```
gemTwoCountryPureExchange_Bond(...)
```

Arguments

...	arguments to be passed to the function sdm2.

Value

A general equilibrium.

Examples

```
es.DFProd <- 0.8 # substitution elasticity between domestic and foreign products
technology.level.CHN <- 1
# the amount of outbound investment corresponding to each unit of consumption
outbound.investment.rate <- 0.1

dst.consumption <- node_new("consumption",
  type = "SCES", alpha = 1, beta = c(0.5, 0.5), es = es.DFProd,
  "prod.CHN", "prod.USA"
)
node_set(dst.consumption, "prod.CHN",
```

```
  type = "Leontief", a = 1 / technology.level.CHN,
  "lab.CHN"
)
node_set(dst.consumption, "prod.USA",
  type = "Leontief", a = 1,
  "lab.USA"
)
dst.CHN <- node_new("CHN",

`ge_tidy` *Tidy a General Equilibrium*

Description

Add names to the matrices and vectors of a general equilibrium, and add demand matrix, demand value matrix and supply value matrix to it.

Usage

```
ge_tidy(ge, names.commodity, names.agent)
```

Arguments

`ge`	a general equilibrium.
`names.commodity`	a character vector consisting of names of commodities.
`names.agent`	a character vector consisting of names of agents.

Value

A tidied general equilibrium.

growth_rate *Compute the Growth Rate*

Description

Compute the growth rates for a vector or each column of a matrix.

Usage

```
growth_rate(x, log = FALSE, first.na = TRUE)
```

Arguments

x	a vector or a matrix.
log	If log==TRUE, the logarithmic growth rate will be computed.
first.na	If first.na==FALSE, the result doesn't contain the first NA.

Value

a vector or a matrix consisting of growth rates.

Examples

```
x <- matrix(1:8, 4, 2)
growth_rate(x)
```

iterate *Iteration Function*

Description

Iteration function

Usage

```
iterate(x, f, times = 100, tol = NA, ...)
```

Arguments

x	the initial state vector. If x has a name attribute, the names will be used to label the output matrix.
f	a user-supplied function that computes the values of the next time.
times	the iteration times.
tol	the tolerance for stopping calculation. If the canberra distance of the last two state vectors is less than tol the calculation will stop.
...	optional arguments passed to the f function.

Value

A matrix consisting of state vectors.

Examples

```
x <- c(1, 2)
f <- function(x, a) prop.table(c(sum(x), a * prod(x)^(1 / 2)))
iterate(x, f, 100, a = 3)
iterate(x, f, 100, tol = 1e-5, a = 3)

#### Heron's method for finding square roots
x <- 1
f <- function(x, n) (x + n / x) / 2
iterate(x, f, 10, n = 5)

#### Find a root of the equation x^3-x-1==0.
x <- 1.5
f <- function(x) (x + 1)^(1 / 3)
iterate(x, f, 10)

####
x <- c(1, 2, 3)
f <- function(x) {
  n <- length(x)
  sigma <- seq(-1, 1, length.out = n)
  result <- rep(NA, n)
  for (k in 1:n) result[k] <- CES(sigma[k], 1, rep(1 / n, n), x, rep(1 / n, n))
  prop.table(result)
}
iterate(x, f, 100)
```

---

makeCountercyclicalProductTax

Make a Countercyclical Product Tax Policy Function

Description

This function returns a countercyclical product tax policy function to accelerate convergence when calculating general equilibrium. In some cases this tax policy with variable tax rates can stabilize the economy (see Li, 2019, section 9.4.5.4) . When a firm's output is higher than the average output in previous periods, a tax is imposed on the firm to reduce the output of the product. Tax revenue will be used for implicit public spending. The way of taxation is to directly deduct a part of the supply of the firm.

Usage

```
makeCountercyclicalProductTax(agent = 1, time.win = c(100, Inf), span = 50)
```

Arguments

agent	a vector specifying the indices or names of firms to be taxed.
time.win	the time window vector, i.e. a 2-vector specifying the start time and end time of policy implementation.
span	a positive integer which indicates the number of periods when calculating the average output.

Value

A countercyclical product tax policy function.

See Also

CGE::Example9.10.policy.tax

Examples

```
ge <- gemCanonicalDynamicMacroeconomic_4_3(
  numberOfPeriods = 1000
)

ge <- gemCanonicalDynamicMacroeconomic_4_3(
  numberOfPeriods = 1000,
  policy = makeCountercyclicalProductTax(time.win = c(500, Inf))
)
```

makePolicyHeadAdjustment

Make a Policy of Head Adjustment for a Timeline Model

Description

Make a policy of head adjustment for a timeline model. Head adjustment refers to the adjustment of the initial product supply to a steady-state value.

Usage

```
makePolicyHeadAdjustment(ind, gr = 0)
```

Arguments

ind	a 4-column matrix or a numeric 4-vector that will be converted into a 4-column matrix. In each row of the matrix, the first element corresponds to the index number of a type of product supplied in the first period, the second element corresponds to the index number of its supplier, the third element corresponds to the index number of the type of product supplied in the second period, and the fourth element corresponds corresponds to the index number of its supplier. Head adjustments are usually made simultaneously with tail adjustments to compute the steady-state equilibrium path. There is usually no need to make head adjustments alone.
gr	the growth rate.

Value

A policy, which is often used as an argument of the function sdm2.

See Also

makePolicyHeadTailAdjustment; makePolicyTailAdjustment

makePolicyHeadTailAdjustment

Make a Policy of Head and/or Tail Adjustment for a Timeline Model

Description

Make a policy of head and/or tail adjustment for a timeline model. A timeline model is an intertemporal non-sequential model that includes production and a given initial product supply. Head adjustment refers to the adjustment of the initial product supply to a steady-state value. Similarly, tail adjustment refers to the adjustment of the share coefficient of the last period of the consumer in the timeline model in order to let the model run in a steady-state equilibrium path.

Usage

```
makePolicyHeadTailAdjustment(
  type = c("both", "tail", "head", "none"),
  gr = 0,
  np
)
```

Arguments

type	a character string specifying the type of the policy, must be one of "both" (default), "head", "tail" or "none". If type=="none", NULL will be returned.
gr	the growth rate.
np	the number of economic periods.

Value

A policy, which is often used as an argument of the function sdm2.

Note

The statement policy = makePolicyHeadTailAdjustment(gr = gr, np = np) is equivalent to policy = list(makePolicyHeadAdjustment(ind = c(1, np, 2, 1), gr = gr), makePolicyTailAdjustment(ind = c(np - 1, np), gr = gr)).

---

makePolicyIncomeTax *Make a Policy of Income Tax*

Description

This function returns a policy function that redistributes the supplies of economic agents, and the effect is equivalent to the collection of income tax.

Usage

```
makePolicyIncomeTax(agent, tax.rate, redistribution, time.win = c(1, Inf))
```

Arguments

agent	a vector specifying the indices or names of taxed agents.
tax.rate	a vector specifying the income tax rates for agents, which has the same length with the argument agent.
redistribution	a vector specifying the proportions of tax revenue received by agents, which has the same length with the argument agent.
time.win	the time window vector, i.e. a 2-vector specifying the start time and end time of policy implementation.

Value

A policy function, which is often used as an argument of the function sdm2.

)
```

`makePolicyMeanValue` *Make a Mean Value Policy Function*

Description

This function returns a mean value policy function with a given span to accelerate convergence when calculating general equilibrium. We can observe the number of periods included in the economic cycle of the time series, and then set the number of periods as the parameter (i.e. span) of this function. See `policyMeanValue`

Usage

```
makePolicyMeanValue(span = 200)
```

Arguments

span	a positive integer. When the time index is an integer multiple of span, the mean value policy sets the current prices and supplies to the averages of the previous span-1 periods.

Value

A mean value policy function.

See Also

policyMeanValue gemDualLinearProgramming.

Examples

```
## See the function gemDualLinearProgramming.

  ts = TRUE,
  policy = makePolicyMeanValue(150)
)
matplot(ge2$ts.q, type = "l")
```

makePolicyStickyPrice *Make a Policy of Sticky Price*

Description

Given a stickiness value and a time window vector, this function returns a policy function that sets the current prices equal to the weighted mean of the market-clearing prices and the current prices during this time window. When the stickiness value is 0, the prices will be set to the market-clearing prices. When the stickiness value is 1, the current prices will keep unchanged.

Usage

```
makePolicyStickyPrice(stickiness = 0.5, time.win = c(1, Inf), tolCond = 1e-06)
```

Arguments

stickiness	a stickiness value between 0 and 1.
time.win	the time window vector, i.e. a 2-vector specifying the start time and end time of policy implementation.
tolCond	the tolerance condition for computing the market-clearing price vector.

Value

A policy function, which is often used as an argument of the function sdm2.

Note

Three major price adjustment methods can be used in the structural dynamic model. The corresponding three kinds of prices are exploratory prices (the default case), market clearing prices, and sticky prices. The exploratory prices are computed based on the prices and sales rates of the previous period. In economic reality, the market clearing prices are unknown, so exploratory prices are more realistic.

When the stickiness value is positive and the priceAdjustmentVelocity parameter in sdm2 is set to 0 (indicating that current prices remain unchanged from the previous period), implementing the sticky-price policy results in current prices that are the weighted average of the market-clearing prices and the prices from the previous period. Typically, this function should be utilized in this manner.

matplot(ge$ts.p, type = "o", pch = 20)
```

---

makePolicySupply *Make a Policy of Supply*

Description

Given a supply matrix and a time window vector, this function returns a policy function that sets the supply during this time window. By default, the time window of this function is c(1, 1), which means that this function will set the initial supply.

Usage

```
makePolicySupply(S, time.win = c(1, 1))
```

Arguments

S	a supply matrix.
time.win	the time window vector, i.e. a 2-vector specifying the start time and end time of policy implementation.

Value

A policy function, which is often used as an argument of the function sdm2.

See Also

sdm2

Examples

```
InitialEndowments <- {
  tmp <- matrix(0, 3, 2)
  tmp[1, 1] <- 0.01
  tmp[2, 2] <- tmp[3, 2] <- 1
  tmp
}

---

makePolicyTailAdjustment

Make a Policy of Tail Adjustment for a Timeline Model

Description

Make a policy of tail adjustment for a timeline model. Tail adjustment refers to the adjustment of the share coefficient of the last period of the consumer in the timeline model in order to let the model run in a steady-state equilibrium path.

Usage

```
makePolicyTailAdjustment(ind, gr = 0)
```

Arguments

ind	a 2-column matrix or a numeric 2-vector that will be converted into a 2-column matrix. In each row of the matrix, the first element corresponds to the index number of the last activity level of producing the product, and the second element corresponds to the index number of a consumer who demands the product in the final period.
gr	the growth rate.

Value

A policy, which is often used as an argument of the function sdm2.

See Also

makePolicyHeadTailAdjustment; makePolicyHeadAdjustment

`makePolicyTechnologyChange`

Make a Policy of Technology Change

Description

This function returns a policy function that changes the attributes alpha and a of the demand structure trees of agents specified. An attribute alpha is usually a parameter of a CES or CD function. An attribute a is usually a parameter of a Leontief function. For demand structure trees that do not contain these two attributes, this function has no effect.

Usage

```
makePolicyTechnologyChange(
  adjumentment.ratio = 1.1,
  agent = 1,
  time.win = c(20, 20)
)
```

Arguments

`adjumentment.ratio`	a scalar. The attributes alpha will be multiplied by adjumentment.ratio. The attributes a will be divided by adjumentment.ratio.
`agent`	a vector specifying the indices or names of agents.
`time.win`	the time window vector, i.e. a 2-vector specifying the start time and end time of policy implementation.

Value

A policy function, which is often used as an argument of the function sdm2.

See Also

  maxIteration = 1,
  numberOfPeriods = 40
)

par(mfrow = c(1, 2))
matplot(ge$ts.z, type = "o", pch = 20)
matplot(ge$ts.p, type = "o", pch = 20)
```

---

marginal_utility *Marginal Utility*

Description

If the argument price is null, this function computes the (delta) marginal utility. By default, delta is set to 1e-10. Otherwise this function computes the (delta) value marginal utility. For a utility function U(x), two vector x, y and a scalar price, the marginal utility is (U(x + delta * y) - U(x)) /

delta, and the value marginal utility is (U(x + delta * y / price) - U(x)) / delta. For a marginal utility function M(x), three vector x, y, wt and a scalar price, the marginal utility is sum(M(x) * y * wt), and the value marginal utility is sum(M(x) * y * wt / price).

Usage

```
marginal_utility(x, y, uf, price = NULL, delta = 1e-10, muf = NULL)
```

Arguments

x	a numeric k-by-m matrix or a numeric vector (i.e. a k-by-1 matrix).
y	a numeric k-by-n matrix or a numeric vector (i.e. a k-by-1 matrix).
uf	a utility function or a list consisting of m utility functions.
price	NULL or a numeric n-vector consisting of prices of each column of y.
delta	a scalar.
muf	a marginal utility function or a list consisting of m marginal utility functions. A marginal utility function is the gradient of a utility function. When the components in the marginal utility vector are the same, a marginal utility function may calculate only one of the components.

Value

An n-by-m marginal utility matrix. Its (i,j)-th element corresponds to the i-th column of y and the j-th column of x.

```

`matrix_add_by_name` *Add Matrices by Names of Columns and Rows*

Description

Add together some matrices by names of columns and rows. Those matrices may have distinct sizes. All matrices should not have column names and row names other than those of the first matrix.

Usage

```
matrix_add_by_name(M, ...)
```

Arguments

`M`	a matrix with column names and row names.
`...`	some matrices with column names and row names which constitute subsets of those of M. If there is a vector, it will be converted to a matrix of one column and the column will be named after the vector.

Value

A matirx.

Examples

```
M <- matrix(0, 5, 5)
colnames(M) <- paste("c", 1:5, sep = "")
rownames(M) <- paste("r", 1:5, sep = "")

M2 <- matrix(1:9, 3, 3)
colnames(M2) <- c("c2", "c3", "c5")
rownames(M2) <- c("r1", "r2", "r4")

matrix_add_by_name(M, M2)

c1 <- c(r1 = 1, r3 = 2)
matrix_add_by_name(M, c1)
matrix_add_by_name(M, c1, M2)
```

---

matrix_aggregate *Aggregate Some Rows and Columns of a Matrix*

Description

Aggregate some rows and columns of a matrix to obtain a matrix with smaller dimensions. This function can be used for aggregating some rows and columns of an input-output table.

Usage

```
matrix_aggregate(
  M,
  row.index = NULL,
  col.index = NULL,
  row.name = NULL,
  col.name = NULL
)
```

Arguments

M	a numeric matrix without NA.
row.index	a numeric vector or a list of numeric vectors indicating the index numbers of rows to be aggregated. The default value is is NULL.
col.index	a numeric vector or a list of numeric vectors indicating the index numbers of columns to be aggregated. The default value is is NULL.
row.name	a character vector or a list of character vectors indicating the names of rows to be aggregated. The default value is NULL. If row.index or col.index is not NULL, row.name and col.name will be ignored.
col.name	a character vector or a list of character vectors indicating the names of columns to be aggregated. The default value is NULL.

Examples

```
M <- matrix(1:16,4,4,TRUE)
colnames(M) <- paste0("c",1:4)
rownames(M) <- paste0("r",1:4)
addmargins(M)

M2 <- matrix_aggregate(M, list(c(1,3),c(2, 4)), 2:3)
addmargins(M2)

M3 <- matrix_aggregate(M, row.name = list(c("r1","r3"),c("r2","r4")), col.name = c("c2","c3"))
addmargins(M3)
```

---

matrix_to_dstl *Convert a Matrix into a Demand Structural Tree List*

Description

Convert a demand coefficient matrix into a demand structural tree list.

Usage

```
matrix_to_dstl(
  x,
  names.commodity = paste("comm", 1:nrow(x), sep = ""),
  names.agent = paste("agt", 1:ncol(x), sep = "")
)
```

Arguments

x	a matrix.
names.commodity	names of commodities. They will be the names of leaf nodes of each demand structural tree.
names.agent	names of agents. They will be the names of root nodes of those demand structural trees.

Value

A demand structural tree list.

Examples

```
A <- matrix(c(
  0, 0, 0, 1,
  8, 6, 1, 0,
  4, 2, 1.5, 0,
  2, 1.5, 0.5, 0
), 4, 4, TRUE)

dstl <- matrix_to_dstl(A)
node_print(dstl[[1]])
```

MDCES_demand *Modified Displaced CES Demand Function*

Description

Compute the modified displaced CES demand function. Firstly, the (unmodified) DCES demand vector and the (unmodified) utility level are computed under the given income and prices. Secondly, the modified beta and es are computed under the unmodified utility level. Finally, the DCES demand vector (namely the modified DCES demand vector) and the utility level (namely the modified DCES utility) are computed under the modified beta, the modified es, the given income and prices.

Usage

```
MDCES_demand(es, beta, xi, w, p, betaMod = NULL, esMod = NULL, detail = FALSE)
```

Arguments

es	the elasticity of substitution.
beta	an n-vector consisting of the marginal expenditure share coefficients (Fullerton, 1989).
xi	an n-vector. Each element of xi parameterizes whether the particular good is a necessity for the household (Acemoglu, 2009, page 152). For example, xi[i] > 0 may mean that the household needs to consume at least a certain amount of good i to survive.
w	a scalar indicating the income.
p	an n-vector indicating the prices.
betaMod	a function with the unmodified utility level u.unmod as the argument.
esMod	a function with the unmodified utility level u.unmod as the argument.
detail	If detail==FALSE, the modified demand vector is returned. If detail==TRUE, the returned vector consists of the modified demand vector, the modified utility, the modified es, the modified beta, the unmodified utility and the unmodified demand vector.

  }
)
```

`node_insert` *Insert Nodes into a Tree*

Description

Scan the tree and insert nodes before the first non-root node having the name specified.
This function is based on the package data.tree and has side-effects. It modifies the tree given by the argument (see the package data.tree).

Usage

```
node_insert(tree, node.name, ...)
```

Arguments

tree	a tree (i.e. a Node object).
node.name	a character string specifying the name of a node. Some nodes will be inserted before it.
...	some Node objects or character strings. A character string will be treated as the name of a new node to be created. Those nodes will be inserted into the tree.

Value

Invisibly returns the parent node of those new nodes.

Examples

```
dst.firm <- node_new(
  "output",
  "prod1",  "prod2"
)
plot(dst.firm)

dst.VA <- node_new(
  "VA",
  "lab",  "cap"
)

node_insert(
  dst.firm, "prod1",
  dst.VA, "prod3"
)
node_set(
  dst.firm, "output",
  "prod4"
)
plot(dst.firm)
```

---

node_new *Create a Tree*

Description

Create a tree by the node_set function and the package data.tree.

As the package data.tree says:

"One of most important things to note about data.tree is that it exhibits reference semantics. In a nutshell, this means that you can modify your tree along the way, without having to reassign it to a variable after each modification. By and large, this is a rather exceptional behavior in R, where value-semantics is king most of the time."

Usage

```
node_new(root.name, ...)
```

Arguments

root.name	a character string specifying the name of the root node.
...	attribute names and values (e.g. alpha=1). The parameter name of a value will be treated as the name of an attribute. A value without a parameter name will be treated as a child node or the name of a child node. If the class of the value is Node, it will be added as a child. If the class of the value is character, a child node (or some child nodes) will be created with the value as the name (or names).

Value

A tree (i.e. a Node object).

Examples

```
#### create a tree
dst1 <- node_new("firm1")
print(dst1)

## create a tree with children
dst <- node_new(
  "firm",
  "lab", "cap", dst1
)
print(dst)

# the same as above
dst <- node_new(
  "firm",
  c("lab", "cap"), dst1
)
print(dst)

#### create a tree with attributes
dst <- node_new("firm",
  type = "CD", alpha = 1, beta = c(0.5, 0.5)
)
node_print(dst)

#### create a tree with attributes and children
dst <- node_new("firm",
  type = "CD", alpha = 1, beta = c(0.5, 0.5),
  "lab", "cap"
)
node_plot(dst)
node_plot(dst, TRUE)
```

node_plot *Plot a Tree and Show the Type Attribute*

Description

A wrapper of the function plot.Node of the packages data.tree. If a non-leaf node has a type attribute, then the attribute will be shown.

Usage

```
node_plot(node, param = FALSE, ...)
```

Arguments

node	a tree (i.e. a Node object).
param	If TRUE, those parameters such as alpha, beta, es etc. will be shown.
...	arguments to be to be passed to the function plot.Node.

See Also

demand_coefficient

node_print *Print a Tree and Its Fields*

Description

A wrapper of the function print.Node of the package data.tree. Print a tree and its fields except the func field.

Usage

```
node_print(node, ...)
```

Arguments

node	a Node object.
...	arguments passed to print.Node.

Examples

```
dst <- node_new("firm",
                type = "SCES",
                alpha = 2, beta = c(0.8, 0.2),
                es = 0.5,
                "wheat", "iron"
)

node_print(dst)

####
dst <- node_new("firm",
                type = "FUNC",
                func = min,
                "wheat", "iron"
)

node_print(dst)
```

---

node_prune *Prune Nodes off a Tree by Names*

Description

A wrapper of data.tree::Prunes. Prune nodes off a tree by names. This function has side-effects, it modifies the tree given by the argument (see the package data.tree).

Usage

```
node_prune(tree, ...)
```

Arguments

tree	a tree (i.e. a Node object).
...	some character strings specifies the names of nodes to be pruned.

Value

Invisibly returns the tree.

Examples

```
dst <- node_new(
  "firm",
  "lab", "cap", "land"
)
node_prune(
  dst,
  "cap", "land"
)
plot(dst)
```

`node_replace` *Replace a Node of a Tree*

Description

Scan the tree and replace the first non-root node having the name specified.
This function is based on the package data.tree and has side-effects. It modifies the tree given by the argument (see the package data.tree).

Usage

```
node_replace(tree, node.name, ...)
```

Arguments

`tree`	a tree (i.e. a Node object).
`node.name`	a character string specifying the name of the node to be pruned off.
`...`	some Node objects or character strings. A character string will be treated as the name of a new node to be created. Those nodes will be added to the tree.

Value

Invisibly returns the parent node of those new nodes.

Examples

```
dst.firm <- node_new(
  "output",
  "prod1", "prod2"
)
plot(dst.firm)

dst.VA <- node_new(
  "VA",
```

```
  "lab", "cap"
)

node_replace(
  dst.firm, "prod2",
  dst.VA, "prod3"
)
plot(dst.firm)

node_replace(
  dst.firm, "lab",
  "labor"
)
plot(dst.firm)

node_replace(
  dst.firm, "VA",
  "prod2"
)
plot(dst.firm)
```

`node_set` *Create a Tree or Set Attributes for a Node*

Description

Create a tree or set attributes for a node by the package data.tree. This function can also be used to add child nodes to a node. This function has side-effects, it modifies the tree given by the argument (see the package data.tree).

Usage

```
node_set(tree, node.name = NA, ...)
```

Arguments

`tree`	a tree (i.e. a Node object) or a character string. If it is a character string, a tree will be created and the string will be the name of the root. And in this case, if you need to use the following parameters to set the attributes of the root node, then the second parameter node.name should be set to NA.
`node.name`	a character string, the name of a node. If the first parameter is a tree, the value of this parameter should be the name of a node in the tree.
`...`	attribute names and values (e.g. alpha=1). The parameter name of a value will be treated as the name of an attribute. If a value is NULL, the corresponding attribute should exist and will be deleted.

A value without a parameter name will be treated as a child node or the name of a child node. If the class of the value is Node, it will be added as a child. If the class of the value is character, a child node (or some child nodes) will be created with the value as the name (or names).

Value

Invisibly returns the node.

See Also

node_new

Examples

```
#### create a tree
dst1 <- node_set("firm1")
print(dst1)

## create a tree with children
dst <- node_set(
  "firm", NA,
  "lab", "cap", dst1
)
print(dst)

# the same as above
dst <- node_set(
  "firm", NA,
  c("lab", "cap"), dst1
)
print(dst)

#### create a tree with attributes
dst <- node_set("firm", NA,
  type = "CD", alpha = 1, beta = c(0.5, 0.5)
)
print(dst, "type", "alpha", "beta")

#### create a tree with attributes and children
dst <- node_set("firm", NA,
  type = "CD", alpha = 1, beta = c(0.5, 0.5),
  "lab", "cap"
)
print(dst, "type", "alpha", "beta")

#### set attributes for a node
dst.firm <- node_set("firm", NA, "VA")
node_set(dst.firm, "VA",
  type = "CD",
  alpha = 0.8^-0.8 * 0.2^-0.2,
```

```
  beta = c(0.8, 0.2),
  "lab",
  "cap"
)
print(dst.firm, "alpha", "beta")

## set attributes and add a child for a node
node_set(dst.firm, "VA",
  type = "SCES",
  alpha = 1,
  beta = c(0.1, 0.8, 0.1),
  es = 0,
  "land"
)
print(dst.firm, "type", "alpha", "beta", "es")

## find a node
x <- node_set(dst.firm, "VA")
node_print(x)
```

`output` *Compute the Utility of a Consumer or the Output of a Firm by the Demand Structural Tree*

Description

Given a demand structural tree and an input vector, this function computes the utility of a consumer or the output of a firm. If the demand structural tree has a FUNC-type node, the node should has an attribute named fun that is a function computing the output.

Usage

```
output(node, input)
```

Arguments

`node`	a demand structural tree.
`input`	an input vector with names of commodities.

Value

A scalar.

Examples

```
dst <- node_new("output",
                type = "SCES", es = 0, alpha = 1, beta = c(0.5, 0.5),
                "cc1", "cc2"
)
node_set(dst, "cc1",
         type = "Leontief", a = c(0.6, 0.4),
         "wheat", "iron"
)
node_set(dst, "cc2",
         type = "SCES", sigma = -1, alpha = 1, beta = c(0.5, 0.5),
         "labor", "capital"
)

node_plot(dst, TRUE)

p <- c(wheat = 1, iron = 3, labor = 2, capital = 4)
x <-demand_coefficient(dst, p)
output(dst, x)

output(dst, c(wheat = 3, iron = 3, labor = 3, capital = 3))
SCES(
  es = 0, alpha = 1, beta = c(0.5, 0.5),
  x = c(
    min(3 / 0.6, 3 / 0.4),
    SCES(es = 0.5, alpha = 1, beta = c(0.5, 0.5), x = c(3, 3))
  )
)
```

---

policyMarketClearingPrice

Market-Clearing-Price Policy Function

Description

This policy is to make the market clear every period. In this case, the path of the economy is the spot market clearing path (alias instantaneous equilibrium path). Generally, this function is passed to the function sdm2 as an argument to compute the spot market clearing path.

Usage

```
policyMarketClearingPrice(time, A, state, ...)
```

Arguments

time	the current time.
A	a demand structure tree list (i.e. dstl, see demand_coefficient), a demand coefficient n-by-m matrix (alias demand structure matrix) or a function A(state) which returns an n-by-m matrix.

state	the current state.
...	optional arguments to be passed to the function sdm2.

Value

A list consisting of p, S and B which specify the prices, supplies and supply coefficient matrix after adjustment.

policyMeanValue *Mean Value Policy Function*

Description

When the time index is an integer multiple of 200, this policy sets the current prices and supplies to the averages of the previous 199 periods. This policy function is mainly used as an argument of the function sdm2 in order to accelerate convergence when calculating general equilibrium.

Usage

```
policyMeanValue(time, state, state.history)
```

Arguments

time	the current time.
state	the current state.
state.history	the state history, which is a list consisting of the time series of p, S, q, and z.

Value

A list consisting of p, S and B which specify the prices, supplies and supply coefficient matrix after adjustment.

See Also

makePolicyMeanValue sdm2 gemDualLinearProgramming.

QL_demand *Quasilinear Demand Functions*

Description

Some quasilinear demand functions. The corresponding utility functions are as follows:
power: x1 + alpha * x2^beta, wherein alpha>0, 0<beta<1.
log: x1 + alpha * log(x2), wherein alpha>0.
quadratic1: x1 + alpha * x2 - 0.5 * beta * x2^2, wherein alpha>0, beta>0.
quadratic2: x1 + beta * (alpha * x2 - 0.5 * x2^2), wherein alpha>0, beta>0.
min: x1 + alpha * min(x2, beta), wherein alpha>0, beta>0.
CRRA: x1 + alpha * (x2^(1 - beta) - 1) / (1 - beta), wherein alpha>0, beta>0. If beta==1, the function becomes x1 + alpha * log(x2).

Usage

```
QL_demand(
  w,
  p,
  alpha,
  beta,
  type = c("power", "log", "quadratic1", "quadratic2", "min", "CRRA")
)
```

Arguments

w	a scalar indicating the income.
p	a 2-vector indicating the prices.
alpha	a scalar.
beta	a scalar.
type	a character string specifying the type of the function. The default type is "power". Other possible values are "log", "quadratic1", "quadratic2" and "min".

Value

A 2-by-1 matrix indicating demands.

Examples

```
QL_demand(w = 0.5, p = c(1, 1), alpha = 1, type = "log")
QL_demand(w = 2, p = c(1, 1), alpha = 1, type = "log")

QL_demand(w = 1, p = c(1, 5), alpha = 2, beta = 0.5)
```

---

rate_to_beta *Conversion between a Rate Vector and a Beta Vector*

Description

Conversion between an expenditure rate vector and a beta vector (i.e. an expenditure proportion vector). For an economic agent, the rate vector indicates the ratios between expenditures on financial instruments and the physical commodity. The first element of the rate vector indicates the quantity of the physical commodity needed to obtain a unit of output. Other elements indicate the ratio of expenditures on various financial instruments to that of the physical commodity, which may be equal to the interest rate, the tax rate, the dividend rate, etc. The beta vector indicates the proportions of expenditures on various commodities.

Usage

```
rate_to_beta(x)

beta_to_rate(x)
```

Arguments

x	a vector.

Value

A vector.

Functions

- `rate_to_beta`: Convert a rate vector to a beta vector.
- `beta_to_rate`: Convert a beta vector to a rate vector. When converting the beta vector into a rate vector, it will be assumed that the first element of these two vectors is the same.

See Also

demand_coefficient

Examples

```
rate_to_beta(c(1, 1 / 3, 1 / 4))
rate_to_beta(c(0.5, 1 / 3, 1 / 4))

x <- beta_to_rate(c(0.7, 0.1, 0.2))
rate_to_beta(x)
```

---

ratio_adjust *Ratio Adjustment*

Description

Adjust ratios to new values.

Usage

```
ratio_adjust(
  ratio,
  coef = 0.8,
  method = c("log", "left.linear", "trunc.log", "linear")
)
```

Arguments

`ratio`	a numeric vector or a positive numeric n-by-m matrix.
`coef`	a positive number, a positive numeric vector or a positive numeric n-by-m matrix. The smaller this value, the closer the adjusted ratio will be to one.
`method`	a character string specifying the adjustment method.

Details

For a positive ratio and the following methods, the return values are as follows:

- log : coef * log(ratio) + 1, if ratio >= 1; 1 / (coef * log(1 / ratio) + 1), if ratio < 1.
- left.linear : 1 / (coef * (1 / ratio - 1) + 1), if ratio >= 1; 1 + coef * (ratio - 1), if ratio < 1.
- trunc.log : max(coef * log(ratio) + 1, 0).
- linear : coef * (ratio - 1) + 1.

Value

A vector or a matrix with dimensions the same as the argument ratio.

Examples

```
ratio_adjust(10, 0.8)
ratio_adjust(0.1, 0.8)

x <- seq(0.01, 2, 0.01)
plot(x, x, type = "l")
lines(x, ratio_adjust(x, 0.8, method = "log"), col = "red")
lines(x, ratio_adjust(x, 0.8, method = "left.linear"), col = "blue")
lines(x, ratio_adjust(x, 0.8, method = "trunc.log"), col = "green")

X <- replicate(3, x)
Y <- ratio_adjust(X, c(0.8, 1, 1.2))
matplot(x, Y, type = "l")
```

SCES *Standard CES Function*

Description

Standard CES function, e.g. alpha * (beta1 * (x1 / beta1)^sigma + beta2 * (x2 / beta2)^sigma)^(1 / sigma) wherein beta1 + beta2 == 1.

Usage

```
SCES(sigma = 1 - 1/es, alpha, beta, x, es = NA)
```

Arguments

sigma	the sigma coefficient.
alpha	the alpha coefficient.
beta	a vector consisting of the beta coefficients.
x	a vector consisting of the inputs.
es	the elasticity of substitution. If es is not NA, the value of sigma will be ignored.

Value

The output or utility level.

Examples

```
beta <- c(0.6, 0.4)
SCES(alpha = 1, beta = beta, x = beta, es = 0.5)
```

SCES_A *Standard CES Demand Coefficient Matrix*

Description

This function computes the standard CES demand coefficient matrix (i.e. Theta==Beta), which is a wrapper of CES_A of CGE package.

Usage

```
SCES_A(sigma = 1 - 1/es, alpha, Beta, p, es = NA)
```

Arguments

sigma	a numeric m-vector or m-by-1 matrix. 1/(1-sigma) is the elasticity of substitution.
alpha	a nonnegative numeric m-vector or m-by-1 matrix.
Beta	a nonnegative numeric n-by-m matrix, where the sum of each column is equal to 1. If a vector is provided, then it will be converted into a single-column matrix.
p	a nonnegative numeric n-vector or n-by-1 matrix.
es	a numeric m-vector or m-by-1 matrix of elasticity of substitution. If es is not NA, the value of sigma will be ignored.

Value

A demand coefficient n-by-m matrix.

Examples

```
SCES_A(-1, 1, c(0.9, 0.1), c(1, 1))
SCES_A(alpha = 1, Beta = c(0.9, 0.1), p = c(1, 1), es = 0.5)
SCES_A(0, 1, c(0.9, 0.1), c(1, 1))
beta <- c(0.9, 0.1)
CD_A(prod(beta^-beta), c(0.9, 0.1), c(1, 1))

####
```

```
SCES_A(0, 1, c(0.9, 0.1, 0), c(1, 1, 1))

####
input <- matrix(c(
  200, 300, 100,
  150, 320, 530,
  250, 380, 0
), 3, 3, TRUE)
Beta <- prop.table(input, 2)
SCES_A(sigma = rep(0, 3), alpha = c(1, 1, 1), Beta = Beta, p = c(1, 1, 1))
SCES_A(sigma = rep(-Inf, 3), alpha = c(1, 1, 1), Beta = Beta, p = c(1, 1, 1))
```

---

sdm2 *Structural Dynamic Model (alias Structural Growth Model) Version 2*

Description

A new version of the sdm function in the package CGE. Now the parameter A can be a demand structure tree list. Hence we actually no longer need the function sdm_dstl. Some rarely used parameters in the function sdm have been deleted. This function is the core of this package.

Usage

```
sdm2(
  A,
  B,
  S0Exg = matrix(NA, nrow(B), ncol(B)),
  names.commodity = paste("comm", 1:nrow(B), sep = ""),
  names.agent = paste("agt", 1:ncol(B), sep = ""),
  p0 = matrix(1, nrow = nrow(B), ncol = 1),
  z0 = matrix(100, nrow = ncol(B), ncol = 1),
  GRExg = NA,
  pExg = NULL,
  numeraire = NULL,
  tolCond = 1e-05,
  maxIteration = 200,
  numberOfPeriods = 300,
  depreciationCoef = 0.8,
  priceAdjustmentFunction = NULL,
  priceAdjustmentVelocity = 0.15,
  trace = TRUE,
  ts = FALSE,
  policy = NULL,
  exchangeFunction = F_Z
)
```

Arguments

A	a demand structure tree list (i.e. dstl, see demand_coefficient), a demand coefficient n-by-m matrix (alias demand structure matrix) or a function A(state) which returns an n-by-m matrix. n is the number of commodity types. m is the number of economic agents. The argument state is a list consisting of time (the current time), p (the current price vector), last.z (the output and utility vector of the previous period), w (the current wealth vector) and last.A (the demand coefficient matrix of the previous period).
B	an n-by-m matrix containing of the output coefficients of producers. Each producer produces one or more commodities. The output of each producer is equal to its activity level multiplied by the output coefficients. Columns corresponding to consumers are usually zeros. If the (i,j)-th element of S0Exg is not NA, the value of the (i,j)-th element of B will be useless and ignored.
S0Exg	an initial exogenous supply n-by-m matrix. If the (i,j)-th element of S0Exg is zero, it means there is no supply, and NA means the exogenous part of the supply is zero and there may be an endogenous supply part. In most cases, this matrix contains NA values but no zeros.
names.commodity	names of commodities. If the parameter A is a demand structure tree list, the values in names.commodity should be the names of those leaf nodes.
names.agent	names of agents.
p0	an initial price n-vector.
z0	an m-vector consisting of the initial purchase levels (i.e. exchange levels) which indicate production levels or utility levels.
GRExg	an exogenous growth rate of the exogenous supplies in S0Exg. If GRExg is NA and some commodities have exogenous supply, then GRExg will be set to 0.
pExg	an n-vector indicating the exogenous prices (if any).
numeraire	the name, index or price of the numeraire commodity. If it is a character string, then it is assumed to be the name of the numeraire commodity. If it is a number without a name, then it is assumed to be the index of the numeraire commodity. If it is a number with a name, e.g. c("lab" = 0.5), then the name is assumed to be the name of the numeraire commodity and the number is assumed to be the price of the numeraire commodity, even though the price of the numeraire commodity usually is 1.
tolCond	the relative tolerance condition.
maxIteration	the maximum number of (outer) iterations. If the main purpose of running this function is to do simulation instead of calculating equilibrium, then maxIteration should be set to 1.
numberOfPeriods	the period number (i.e. the number of inner iterations) in each (outer) iteration, which should not be less than 20.
depreciationCoef	the depreciation coefficient (i.e. 1 minus the depreciation rate) of the unsold products.

`priceAdjustmentFunction`
: the price adjustment function. The arguments are a price n-vector p and a sales rate n-vector q. The return value is a price n-vector. The default price adjustment method is p * (1 - priceAdjustmentVelocity * (1 - q)).

`priceAdjustmentVelocity`
: a scalar or an n-vector specifying the price adjustment velocity.

`trace`
: if TRUE, information is printed during the running of sdm2.

`ts`
: if TRUE, the time series of the last outer iteration are returned.

`policy`
: a policy function or a list consisting of policy functions and/or policy function lists. A policy function has the following optional parameters:

  - time - the current time.
  - A - the same as the parameter A of sdm2. When A is a demand structure tree list, it needs not be returned after it is adjusted.
  - state - the current state, which is a list. state$p is the current price vector with names. state$S is the current supply matrix. state$last.z is the output and utility vector of the previous period. state$B is the current supply coefficient matrix. state$last.A is the demand coefficient matrix of the previous period. state$names.commodity contains the names of commodities. state$names.agent contains the names of agents.
  - state.history - the state history, which is a list consisting of the time series of p, S, q, and z.

  The return value of the policy function other than a list will be ignored. If the return value is a list, it should have elements p, S and B which specify the prices, supplies and supply coefficient matrix after adjustment. A vector with the name current.policy.data can be put into the state list as well, which will be put into the return value of the sdm2.

`exchangeFunction`
: the exchange function.

Details

In each period of the structural dynamic model, the economy runs as follows.
Firstly, the new price vector emerges on the basis of the price vector and sales rates of the previous period, which indicates the current market prices.
Secondly, outputs and depreciated inventories of the previous period constitute the current supplies.
Thirdly, policy functions (if any) are implemented.
Fourthly, the current input coefficient matrix is computed and the supplies are exchanged under market prices. The exchange vector and sales rate vector are obtained. Unsold goods constitute the inventories, which will undergo depreciation and become a portion of the supplies of the next period. The exchange vector determines the current outputs and utility levels.

Value

A list usually containing the following components:

- tolerance - the relative tolerance of the results.
- p - equilibrium prices.

- z - equilibrium purchase levels (i.e. production levels or utility levels).
- S - the equilibrium supply matrix at the initial period.
- growthRate - the endogenous equilibrium growth rate in a pure production economy.
- A - the equilibrium demand coefficient matrix.
- B - the supply coefficient matrix.
- S0Exg - the initial exogenous supply n-by-m matrix.
- D - the demand matrix.
- DV - the demand value matrix.
- SV - the supply value matrix.
- ts.p - the time series of prices in the last outer iteration.
- ts.z - the time series of purchase levels (i.e. production levels or utility levels) in the last outer iteration.
- ts.S - the time series of supply matrix in the last outer iteration.
- ts.q - the time series of sales rates in the last outer iteration.
- policy.data - the policy data.

Note

In the package CGE, the spot market clearing path (alias instantaneous equilibrium path) is computed by the function iep. In this package, the instantaneous equilibrium path can be computed by the function sdm2 with the parameter policy equal to `policyMarketClearingPrice`.

The order of implementation of various policies is critical. When a policy list contains a supply policy, a technology (i.e. dstl) policy, a price policy (e.g. a market-clearing-price policy) and a B policy (i.e. a policy adjusting the argument B), both the supply policy and the technology policy should be placed before the price policy, and the B policy should be placed after the price policy. The reason is that the calculation of the current prices may require the use of supply and technology, while the calculation of B may require the use of the current prices.

`sdm_dstl` *Structural Dynamic Model (alias Structural Growth Model) with a Demand Structure Tree List*

Description

This is a wrapper of the function CGE::sdm. The parameter A of CGE::sdm is replaced with a demand structure tree list. This function can be replaced by the more comprehensive function `sdm2`, so it is not recommended.

Usage

```
sdm_dstl(dstl, names.commodity, names.agent, ...)
```

Arguments

`dstl`	a demand structure tree list.
`names.commodity`	names of commodities.
`names.agent`	names of agents.
`...`	arguments to be passed to the function CGE::sdm.

Value

A general equilibrium, which is a list with the following elements:

- D - the demand matrix.
- DV - the demand value matrix.
- SV - the supply value matrix.
- ... - some elements returned by the CGE::sdm function

sserr *Compute the Return Rate in the Steady State Equilibrium*

Description

Compute the (postpaid) return rate in the steady state equilibrium.

Usage

```
sserr(eis, Gamma.beta, gr = 0, type = "CES", prepaid = FALSE)
```

Arguments

eis	a positive scalar indicating the elasticity of intertemporal substitution in the intertemporal utility function.
Gamma.beta	a positive scalar indicating the subjective discount factor, which is typically no greater than 1.
gr	a non-negative scalar indicating the growth rate in the steady state equilibrium.
type	a character indicating the type of the intertemporal utility function, which may be CES (i.e. CRRA) or SCES.
prepaid	a logical value. If prepaid is FALSE, the return rate is returned. Otherwise the prepaid steady-state equilibrium return rate (i.e. the current yield rate) is returned.

Examples

```
sserr(eis = 1, Gamma.beta = 0.97, gr = 0)
sserr(eis = 1, Gamma.beta = 1.25, gr = 0)
sserr(eis = 1, Gamma.beta = 0.97, gr = 0, type = "SCES")

sserr(eis = 0.5, Gamma.beta = 0.97, gr = 0)
sserr(eis = 0.5, Gamma.beta = 0.97, gr = 0, type = "SCES")
```

`structural_function` *Structural Function*

Description

A structured function is a kind of kinked (piecewise) function generated by connecting two functions through a transition region. This function calculates the value of a structured function.

Usage

```
structural_function(theta, transition.interval, f1, f2, ...)
```

Arguments

`theta`	the track switching parameter, which is a scalar.
`transition.interval`	a 2-vector.
`f1`	the first function (or a value).
`f2`	the second function (or a value).
`...`	parameters of f1 and f2.

Value

The value of the structural function.

Examples

```
x <- seq(1, 5, 0.1)
y <- c()
for (theta in x) y <- c(y, structural_function(theta, c(2, 3), log, sqrt, theta))
plot(x, y)
lines(x, log(x), col = "blue")
lines(x, sqrt(x), col = "red")

####
f <- function(theta) {
  p <- c(1, 1)
  structural_function(
    theta,
    c(15, 20),
    function(p) CD_A(alpha = 5, Beta = c(0.6, 0.4), p),
    function(p) CD_A(alpha = 15, Beta = c(0.3, 0.7), p),
    p
  )
}

tmp <- sapply(1:25, f)
matplot(t(tmp), type = "l")
```

var.p *Population Variance and Population Standard Deviation*

Description

The function var.p computes a population variance. The function sd.p computes a population standard deviation.

Usage

```
var.p(x, wt = rep(1, length(x)), na.rm = FALSE)

sd.p(x, wt = rep(1, length(x)), na.rm = FALSE)
```

Arguments

x	a numeric vector.
wt	a numeric vector of weights. By default all elements of x are given the same weight.
na.rm	a logical value indicating whether NA values should be stripped before the computation proceeds.

Functions

- var.p: Population variance.
- sd.p: Population standard deviation.

Examples

```
var.p(1:6)

var.p(x = 1:5, wt = 6:10)
var.p(x = rep(1:5, 6:10))

sd.p(x = 1:5, wt = 6:10)
sd.p(x = rep(1:5, 6:10))
```
